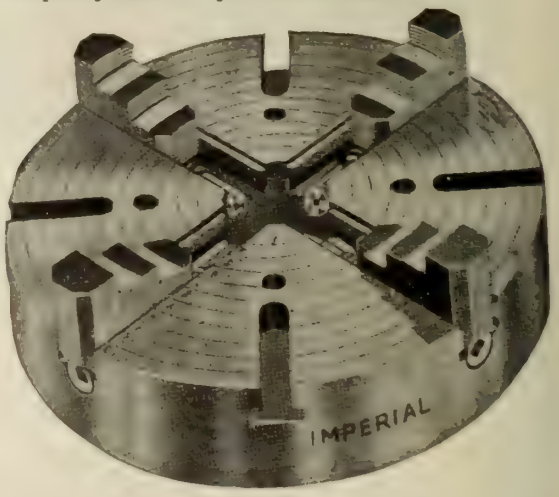
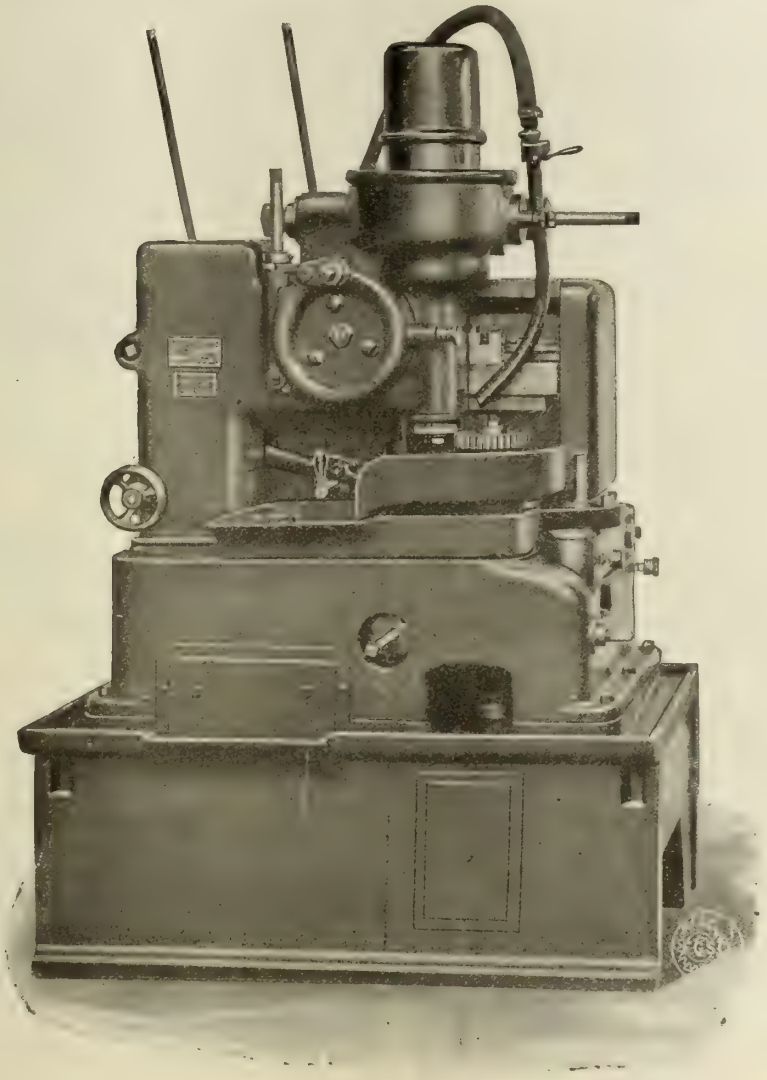
Highly Endorsed by Canada's Best Manufacturers

Sturdy long-wearing "Made-in-Canada" Chucks that are making good everywhere. Specify them in your next order.



Ker & Goodwin Machinery Co. LIMITED
BRANTFORD, Ont.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper



The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical magazines
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

The Hammer With The Human Stroke

HEADS RIVETS COLD

Heads 'em tight or loose, flush, countersunk, or finishes heads any shape desired, and at the rate of:
A rivet a second, sizes up to 3/16".
A rivet in two seconds, size ¼" to ⅜".
A rivet in three seconds, size 7/16" to ⅝".
And on special order we build machines to handle rivets up to 1½" with proportionate rapidity.
Built in eight sizes.
Besides riveting, the High Speed Riveting Hammer does all kinds of peining, swaging, upsetting, etc.
Send us sample assembly parts with rivets or sketch of your work,
and
Let us shoulder your riveting problems.
Send for the High Speed Hammer Book.

INTERNATIONAL
FOUNDRY TRADES EXHIBITION
BIRMINGHAM
June 15th—24th, (inclusive)

Engineering Production

The British Journal of Works Practice and Administration Circulating throughout the World will publish in the issues of

JUNE 8th, 15th & 22nd,

an authoritative description of the leading exhibits at the above Exhibition.

The equipment of the foundry with modern plant and appliances is becoming more and more recognized by engineers as a matter of great importance in economical production.

Those situated in various parts of the world who are interested in, but unable to visit the Exhibition, will find these issues of great value in giving information regarding the latest developments in foundry practice.

These issues will contain further instalments of the series on
WELDING AND CUTTING
and also many articles of an interesting production character, as well as the regular features such as the review of inventions, foreign trade notes and metal markets, etc.

EVERY THURSDAY 6d.

Subscription Rates: United Kingdom, 32 6 (Canada 32 6) Other countries abroad, 36 10, per annum, post free.

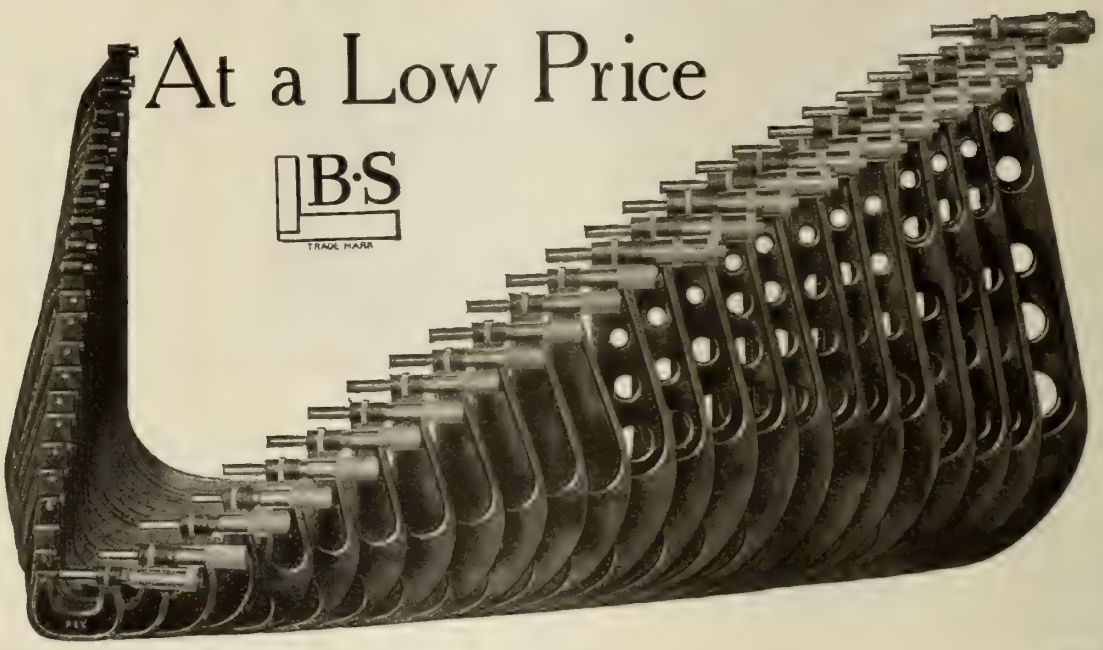
REX—A Complete Line of BROWN & SHARPE MICROMETERS

At a Low Price



The Tools You've Been Looking For

Weeks, maybe months ago, you started looking for a set of Micrometers. You needed them then; you may need them now. A good set of Micrometers means better work and a reputation for speed and accuracy.

When you began to investigate, you found two good reasons for not buying the set you needed so badly. First of all, the high-grade tools whose accuracy met your requirements seemed a bit high-priced, and you quite properly refused to buy inferior tools. So you let the matter stand.

But NOW you can get the tools you've always wanted—accurate Micrometers at a low price. Ask your dealer to show you

REX MICROMETERS

the latest Brown & Sharpe Tools. This complete line of Rex Micrometers gives you, at a low price, the high accuracy found in every Brown & Sharpe Tool. These high-grade, inexpensive Rex Micrometers come in 24 sizes, covering a range from 0 to 24″.

Rex Micrometers are fully listed in our illustrated circular, which also describes the Rex Micrometer Sets. Ask your dealer for this circular and select the set you require, or fill out this coupon and send it to us direct.

Increasing the Efficiency of Railroad Cars

Express locomotive equipped with roller bearings and operating successfully on Swedish State railway.

By J. H. MOORE

THE QUESTION of "railway bearings" has been one of general interest among railroad executives for some time past. This question has often been asked, "Shall we stick to the regular old style bearing, or shall we install ball or roller bearings?"

Unfortunately, for the sake of progress, nothing much has been accomplished except talk by certain railways, but in other cases trials have been made with roller and ball bearings with splendid results.

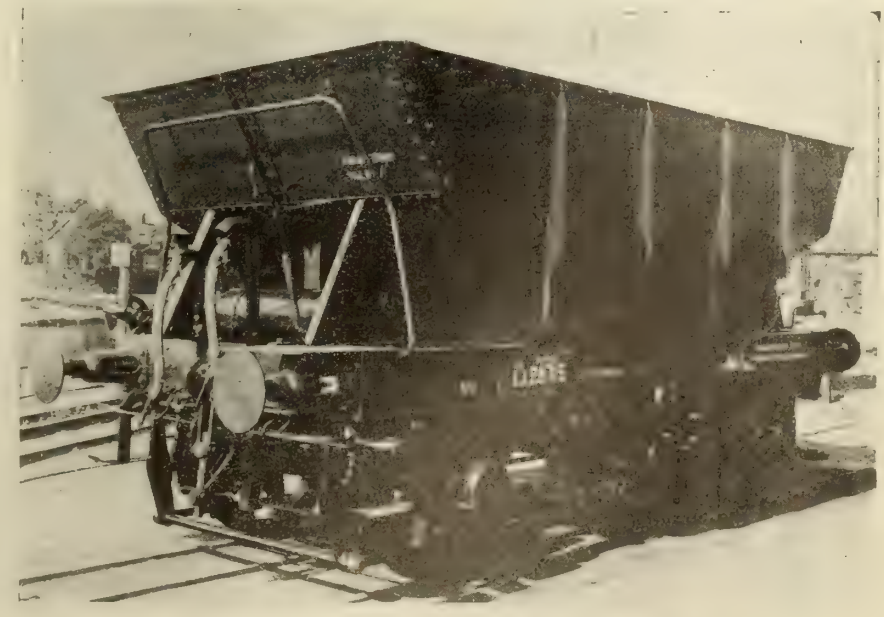
Up to the present time railway men have been cautious in condemning or upholding the use of roller bearings in place of the regular type. A few have openly stated they believed some improvement should be made, while others again have questioned the safety, durability and expense of the former type mentioned. Severe tests have been made from time to time, and now, it looks as if the doubters were soon to be silenced, because the Royal Board of Railway directors in Stockholm, Sweden, have decided to equip a large number of their cars with roller bearings. This is a very important decision, and was only arrived at after exhaustive tests, which have proved even more satisfactory than expected. In every case the applications tested have been found to fill the strictest requirements. Feeling this matter to be of vital interest to our readers we have secured details of the type of equipment to be used, also the tests made, and will take up the points in sequence.

The Tests Made

During the latter part of 1921, eight bogie cars, with altogether 32 axles in roller bearings, were put into express train service on the State railways. The journal pressure was about 5½ tons, and one spherical and one cylindrical roller bearing were used. The speed at which these cars ran was approximately 56 miles per hour while the cars covered about 124,200 miles per year. So far there have been no rejections.

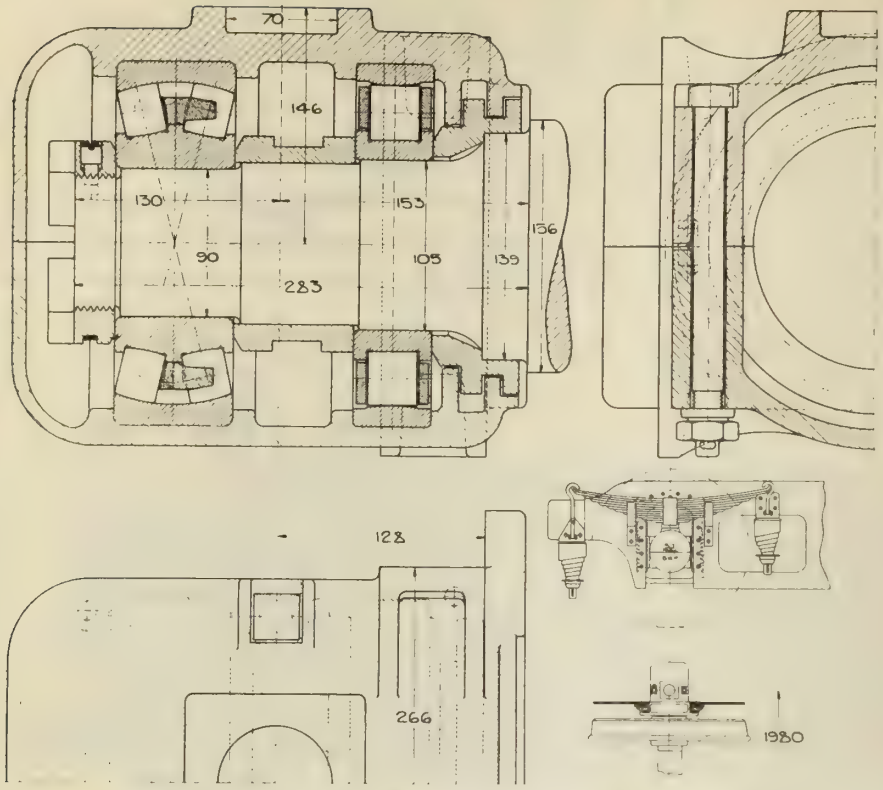
A test was also made on locomotive axles, and two of these have been running for the past two years. Each box was equipped with one spherical roller bearing, and one of the cylindrical type. The journal pressure was 6½ tons, and again there were no rejections.

Other important trials have been



Ore wagon equipped with roller bearings for Swedish State railway.

Information, photographs and drawings through the courtesy of the Canadian S.K.F. Co., Toronto. Tests mentioned were made by the parent company in Sweden, who have been making an exhaustive study of this subject for many years, and were successful in closing the important order spoken of in the article.



Sectional view showing application of roller bearing to bogie axle.

made in Sweden, the results being as follows:—Ball bearings are now in use in three bogie cars on the Bergslagarnas railway, the application being similar to that of the State railway.

On the line Gellivaare-Lulea, about 124 miles, the coal consumption for the trip with a loaded ore train consisting of 39 ball bearing wagons, and return trip with the same train but empty showed less than 10 tons. The water consumption was approximately 2,079 cub. ft. The corresponding figures for a train of only 30 cars on plain bearings were, coal consumption 10 tons, and water 2,360 cub. ft. These figures give the average for 5 round trips and show that it was possible to increase the number of wagons by about 30 per cent. with the same consumption of coal and water.

On ore traffic with electric locomotives on another line it was found that the same current consumption on the motors was registered for 30 wagons on plain bearings, as against 35 on ball bearings. In other words 17 per cent. more cars used without additional current consumption. Another coal saving test made on the Stockholm-Mjolby line, with plain and ball type of bearings showed a saving of 10 per cent. for the latter.

Two flexible axle cars equipped with two ball bearings in each box, were put into passenger train service on the Danish State Railways in 1914. The journal pressure in this case is about 5 tons, and the cars run about 186 miles per day, with a maximum speed of 56 miles per hour. Even up to present date no rejections have occurred, and the cars are still in traffic. Other trials have been made with roller bearings in Great Britain, Australia, and Czecho-Slovakia, etc., and from actual cost records it has been found that roller bearings in bogie cars usually pay for themselves in four years through the saving in coal alone.

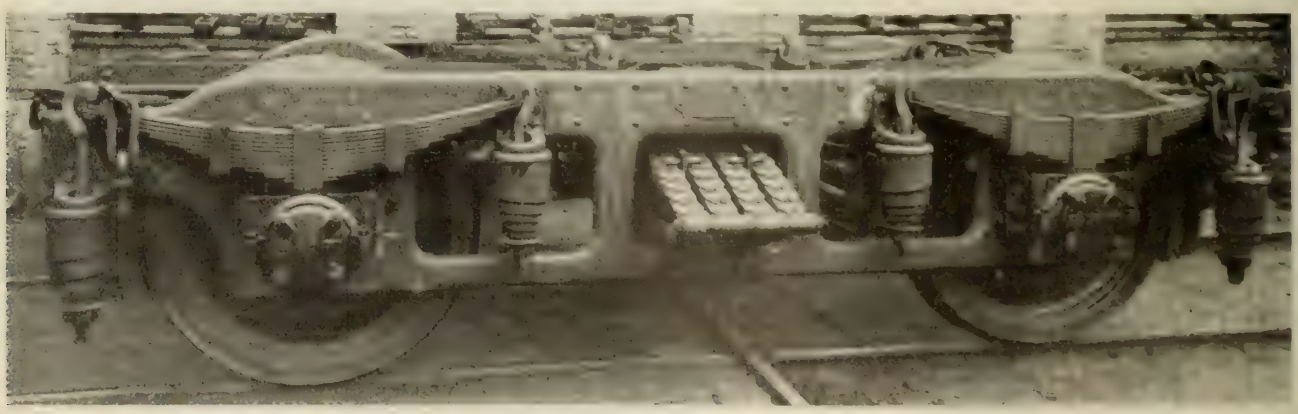
It was largely as a consequence of the favorable results attained in the trials run in Sweden that the latest decision was arrived at by the Royal Board, and 1,360 boxes, or 2,720 roller bearings for bogie cars have been ordered for the new applications. Other railways have ordered roller bearing boxes for ore wagons etc., so that the movement appears to be general in character.

The Great Eastern Railway Co., of Great Britain, have just concluded a successful series of preliminary trials with roller bearings applied to passenger trains and speaking about this subject, the engineering editor of the Manchester Guardian, has the following to say:

"It is surprising that ball or roller bearings have not been applied on an extensive scale to railway work years ago, in spite of the severe conditions of working. A long train, especially when composed of the small 10-ton wagons characteristic of British railways, with its large number of wheels and bearings, each of which takes heavy toll of the power transmitted, combining with the frequent stops and consequent heavy starting loads, is an ideal field for the application of modern anti-friction devices. It is perhaps even more surprising that the engineering industry in general has also not yet realized the enormous advantages of ball and roller bearings in eliminating friction losses, which are so serious that in many cases over 20 per cent. of the total power generated is lost.

"The textile industry, for example, is a suitable field for the application of ball bearings. In the case of the main lines of shafting equipped with ordinary plain bearings the loss of friction is 15 to 30 per cent. of the power transmitted. It would not be exaggerating to say that the installation of modern ball bearings would pay for itself in less than 12 months, whilst as regards individual machines the application of ball bearings would save something like 10 to 12 per cent. of the power required, taking an average of all the various types of machines in use in the textile industry.

"The application of ball and roller



Bogie equipped with roller bearings and used on Swedish State railways.

bearings to railway work is not, however, a new idea. Elaborate experiments, dating back to at least eight years ago, have been undertaken by the University of Illinois, U. S. A., and by several firms in this country who have specialized for many years in the manufacture of every description of anti-friction bearings. Most of these tests were carried out on goods wagons, with results so satisfactory that there is no reason why passenger vehicles should not also be fitted.

"As an indication of the high efficiency of ball and roller bearings as applied to railway conditions, the average running resistance for ordinary goods wagons at speeds up to 30 miles per hour was found to be, with the ordinary bearings 3.62 lb. per ton, whilst with modern ball bearings the figure was reduced to 2.2 lb. per ton, or, in other words, the power required to haul a running train was reduced by no less than 38 per cent. This is, however, not the only advantage. The starting up of a train requires a very heavy initial pull to overcome the standing friction, and the installation of ball and roller bearings reduces this initial frictional resistance by as much as 85-90 per cent.

Weather Conditions Overcome

"A still further advantage for railways is the fact, as determined with great accuracy in the Illinois experiments, that with ordinary common bearings the weather causes a great difference in the frictional resistance, as much as 30 per cent. between extreme summer and winter conditions, and certainly it averages 10 per cent. This difference is practically eliminated with ball and roller bearings. Ball bearings give more efficient results than the roller variety, but the latter, which can be said to save something like 14-20 per cent. of the tractive load, are more resistant to wear and tear. The stress of bearings of this description is, however, a difficult proposition, because, of course, at any given fraction of a second the strain is very severe, since the load is being carried by only a very small point of the total area.

"In fact, both ball and roller bearings must fulfil the onerous conditions of being a self-contained unit, without any loose parts and not requiring adjustment, of being able to take a radial load, combined with a very high fatigue limit, the lowest possible friction, and absence of vibration. To cope with these severe requirements the metal used is a very high grade, hard, carbon chrome steel, made from the finest Swedish iron, and in general the manufacture of such bearings has been advanced to such a degree of accuracy and organization that it can justly be termed one of the triumphs of modern engineering. It is an encouraging sign that railway companies, notoriously conservative in their ideas, should be turning at last to such modern methods, and further details of the Great Eastern experiments will be awaited with interest."

From the foregoing it will be seen that the railways in the Old Country are looking ahead, and it is stated on good authority, that if further investigations prove satisfactory, and it is fully expected they will, the whole of the Great Eastern rolling stock will be fitted with roller bearings. What Canadian roads will do in the future remains to be seen, but friction is a deadly enemy which must be overcome, and the sooner we grapple seriously with the problem, the better it will be for all concerned.

Taking Moisture From Compressed Air

Moisture is mixed with air in the form of perfectly transparent and invisible vapor, until a humidity of 100 per cent., or the point of saturation, or the dew point, is reached and this dew point is always reached in compression and transmission of air at ordinary working pressures, say six atmospheres or 75 lb. gauge. Immediately when this point is passed, the excess moisture condenses into actual water but is still mixed with air. The saturation point of air constantly varies, and is determined by its pressure and temperature, especially the latter and, at a fixed temperature, any given volume of air is saturated when it contains a certain quantity of water vapor. Now, if the absolute pressure of a certain quantity of air is, say doubled, by which the volume is reduced ½, the moisture carrying capacity is reduced the same proportion so that if the humidity of free air is 50 per cent., this humidity becomes 100 per cent. when air is compressed to two atmospheres (15 lbs. gauge) and if compressed to six atmospheres (75 lbs. gauge) the humidity becomes 300 per cent., and 200 per cent., of the air will refuse to carry water as vapor if the temperature remains constant.

As air is compressed its temperature rises rapidly and with each rise of about twenty degrees its capacity for carrying moisture is doubled. Starting with free air at sixty deg.; as it is compressed to 75 lbs. gauge, its temperature at delivery no matter how perfectly the compressor cylinder may be water jacketed, will be about 300 deg., so that in consequence of this change of temperature, the capacity of the air for moisture will have been doubled so many times that when it leaves the cylinder the real humidity will be quite low although it still carries all the moisture with which it started.

When the air is lowered in pressure, as is the case when being used for operating pneumatic tools, air rammers, or any other use where the kinetic energy is converted into work, this excess moisture will show up in the form of water and the water content will be very noticeable where the air is delivered into much lower temperature than that at the compressor. If however this compressed air is pre-cooled to a temperature not in excess of that of the point of delivery or usage, the moisture will be precipitated at the point of pre-cooling and a separator placed between the pre-cooler and point of delivery will eliminate the moisture and deliver dry air, provided the moisture removed does not in any way come in contact with the air passing through the separator.

In many cases there is sufficient cooling surface in the pipe line, which is exposed to atmospheric temperature, that it is not necessary to install after-cooler; however the following tables will enable you to determine whether or not there is sufficient cooling surface in the pipe line or if after-cooler is required the approximate size can be figured from the table showing required cooling surface for free air delivered. The following table shows the length of pipe containing one square foot of cooling surface:—

Size, External	Surface, Internal	Surface
¾ in	3.637	4.635
1 in.	2.904	3.645
1¼ in.	2.301	2.768
1½ in.	2.01	2.371
2 in.	1.608	1.848
2½ in.	1.328	1.547
3 in.	1.091	1.245
3½ in.	.955	1.077
4 in.	.849	.949
4½ in.	.764	.848
5 in.	.687	.757
6 in.	.577	.63
7 in.	501	.544
8 in.	.443	478
9 in.	.397	.427
10 in.	.355	.382

* As suggested by the United Machine and Mfg. Co.

PILFERING GOODS IN TRANSIT

Some amazing instances of pilferage of goods in transit have just come to light, says a report from the Old Country. The reports show that the thieving of goods has now become a fine art. Numerous instances have lately been reported from various parts of the world of the delivery of cases in apparently perfect condition which, when opened, were found to contain rubbish instead of valuable goods. Thefts of this kind have given rise to the suggestion that somewhere in the course of transit identical cases have been made and marked, and substituted for the original cases containing the real merchandise. Cases have arrived in such perfect condition that the only other explanation offered is that the goods ordered were never actually packed in them. That there have been numerous instances of such practices is generally believed in shipping and insurance circles. One way, it is suggested, of putting a stop to wrongdoing of the kind would be for underwriters to require their merchants to be privy to the correct packing of the goods. If it could be proved—and it would not always be an easy matter to do so—that goods were never packed, the merchants would have to bring the responsibility home to the suppliers of the merchandise.

Baldwin's Steel May Extend Tin Plate Operations

Decision on Future Plans End of October—Investment of Four Millions—Rail Strike a Chief Cause of Suspension—Problems of Building up Force—Drawback Allowed on Materials

WHILE Baldwin's Canadian Steel Corporation Limited, Toronto, are suspending operations largely as the result of transportation difficulties in securing adequate supplies of materials, it is stated that no definite plans for the future may be made known until the end of October. The president, Capt. Hugh C. Paynter, states that it may be decided to increase the capacity of their tinplate mill and make other extensions that will still further appreciate the requirements of the Canadian market.

Meantime, some regret is expressed that so large and important an industry and one for which there is so definite a field in this country should find it necessary to close out, if only for the time being. Conditions, however, should gradually right themselves, making it possible for this huge plant to resume.

In their two years' existence here the company has expended something like $4,000,000, and undoubtedly has had to contend with many of the problems that confront an infant industry. Labor conditions here differ widely from those of the Old Country where industrial heredity has made skilled men available whose families have been identified with specific callings for generations. Here, such men have to be trained. This is quite a task, for there are many classes of work in which an easier living may be made than in the production of black sheets of tin plate. There is no specialized field to draw from. The human element is a big factor in plate production and in building up a force, it is important that men appreciate the responsibilities of their departments. When this is not the case it might, for example, be a comparatively easy matter for a workman to cause a loss of upwards of $5,000 by deserting his post for some trivial cause, thereby allowing a pot of metal to burn. Absolute dependability upon the human factor is therefore essential. Some headway has been made.

Problems Being Adjusted

Press reports intimate that the cause of suspension was to a large extent due to unfulfilled promises as regards the tariff and local assessments. This is hardly the case. The company's original assessment was $2,000,000, which was subsequently reduced to $785,000. Negotiations are under way looking to a fixed assessment.

Competition with American produce is keen, and so far as tariff is concerned there is not likely to be an early revision, but the company has found itself in a better position in this respect recently by obtaining recognition of a clause in the tariff of 1908 by which a drawback of 99 per cent. is provided upon all imported materials entering into the manufacture of tinplate. This was a provision that was introduced by way of encouragement to an earlier Canadian plate industry, but which has evidently remained dormant as having no application after the cessation of the industry. Included in the materials covered in this way are rolls, classified as castings, and representing quite an item in tinplate manufacture. The drawback applies to the operations of the company since their beginning in Canada. Items entering into the production of plate sheet include crude oil, requiring one carload per day; coke, one carload per week, and large quantities of palm oil and grease, to say nothing of large metal tonnages necessary.

Running under normal conditions the plant has employed as high as 600 men. During their closing out activities they have something less than two hundred. In encouraging youths to enter the industry they have been paying to start 25 cents an hour, which is equivalent to the wage received by many skilled mechanics in the Old Country.

Requirements of the plant in electric horse power are high and the monthly bill considerable. Among those matters that would seem to call for readjustment is an item of 1660 per month for a power line which the company's operations have never called into service. The plant in some respects is self-contained and not altogether dependent upon certain municipal services.

Business men, engaged in iron and steel activities, express the hope that this important industry, so well equipped to fit in with the requirements of the market, may shortly find it possible to carry on.

Ores, Woods, Implements Needed In Hungary's Rehabilitation

HAVING suffered frightful dismemberment during the war, with all valuable assets taken away and her rolling stock given to Rumania, where much of it is rusting and rotting unused, a gigantic task has confronted Hungary in her work of rehabilitation. Materials of various kinds are urgently needed, particularly woods for furniture and kindred industries; ores, chiefly iron, and certain agricultural implements which Canada can supply.

This is the observation of Col. J. B. MacLean, president MacLean Publishing Co., Toronto, who, during a recent trip to Europe, spent three weeks in Czecho-Slovakia. Frequent few-minute chats with a number of business, financial and political leaders afforded an insight into National problems. Among those whom he thus met was one who, a few years ago, delivered an address at Toronto University, and who, for many years, occupied one of the most prominent positions in Austria-Hungary. Mainly interested in the rehabilitation of his country at the present time, he is very optimistic as to its future. Hungary, he points out, is most desirous of retaining her agricultural population and her highly trained artisans who are fairly prosperous, but there are many well-educated mechanics, teachers and professional men of whom not a few are being supported today by charity mainly contributed by British and United States friends. Many of these would go to Canadian farms, and there are thousands of hard-working women available for domestic service.

The kingdom of Hungary, which is the oldest and, previous to the war, probably the most prosperous country in Europe, had perhaps, the least sympathy of any for the war. This is shown by the fact that over one hundred thousand of their army deserted the Germans and joined the Russians, to be in turn deserted by them, and they finally joined the Canadian forces at Vladivostock and about twenty-five thousand of them were taken back to their own country via Canada.

Good work done by the Canadian Pacific Railway in the two or three years just before the war has made the people of Hungary very friendly toward this country. All who can, want to emigrate to Canada. Inducements offered by Americans are frequently met with the suggestion that they would prefer Canada. A number of generous Americans, who visit Carlsbad and other parts of Czecho-Slovakia and Hungary, have offered to pay the expenses of certain former Hungarians and several have taken advantage of this.

"I think that Hungary would be quite ready to give very reasonable terms, perhaps free trade, to Canada in implements, ores and woods in exchange for similar concessions," said Col. MacLean. "That, however will be for the industries interested to put before the sympathetic attention of Hon. Mr. Robb, Minister of Trade."

Machining the Stutz D.H. Motor Cylinder and Head

Jigs and Fixtures Used in Holding the Parts—Twelve Cylinders Milled at One Setting—Pieces Easily and Quickly Located by Means of Sliding Supports and Spring Dowels

By ROBERT MAWSON

MACHINING operations on automobile cylinders involve some interesting methods of holding the work while the milling, drilling and boring are being performed. The views here shown illustrate some of the jigs and fixtures used in accomplishing several of the more important details in machining the blocks and heads for the Stutz detachable head motor.

After the cylinders have been inspected and given the hydraulic test to ascertain if the castings are perfect, the first machining operation is performed on an Ingersoll milling machine. The table and fixtures placed on this machine will accommodate 12 cylinders at one setting. These are pushed back against stop pins and also rest on height pins so that the surfaces to be milled will be square. Clamps are then tightened onto the pieces to hold them securely in the fixtures, the design of which can be clearly seen by referring to Fig. 1. With the castings held as shown, six faces are milled at once, namely, top and bottom of the cylinder and four surfaces on the exhaust and intake side. For this work three 11-inch, two 5-inch and one 8-inch cutters are used and their type may be seen by referring to the illustrations.

Drilling Stud Holes—Crank Case Side

The next operation is drilling the holes used to fasten the cylinder to the crank case. This is performed with the jig illustrated in Fig. 3. The jig is first swung over, after it has been brought forward on the tracks A, being indexed by means of the handle operating a pin which fits into the hole B. The cylinder is then pushed into the jig, being located with stop pins at the rear and on the side; set screws are then tightened against the casting to hold it against the locating mediums. Straps at C are then fastened as shown to hold the piece securely during the machining operation. Ten 9/16 inch holes are then drilled, two of the holes being afterwards reamed, these latter holes being used in locating the cylinder in subsequent operations. The jig illustrated is the tool used for this drilling; some of the drills are not operated, but those used may be ascertained by noting the guide bushings in the jig. The tool is then swung over as described when the casting may be easily removed by loosening the straps and set screws.

Boring the Cylinder

The next operation is machining the bores to suit the pistons, and this work is performed with equipment as shown in Fig. 3. The casting is located by means of two dowels which fit into the holes previously reamed; the two wedges A are then driven under the piece and these raise it up, holding it in position in the fixture. The cylinder is bored in three separate machines, the fixtures, method of locating and holding are similar to that illustrated. The holes are bored to 4.260 inches in the first setting, 4.330 inches in the second and 4.365 inches in the third. The four holes are ground to 4.375 in a subsequent operation in order to obtain smooth and round surfaces. For the boring operations the bars are guided through the long bearings shown on the upper surface of the fixture in order to obtain parallel holes; as the casting is held and located from the base parting line surface the holes are at right angles to this surface. After the holding wedges have been removed the casting may be slid on the track B and taken out easily from the fixture.

The open ends of the bores are then chamfered with the set up shown in Fig. 4. For this operation the cylinder is moved under the tool A which, it will be observed, has a pilot end to locate it in the cylinder bores and thus enable the chamfered surface to be produced square with the milled faces and holes.

Drilling and Reaming Valve Holes

The next operation is drilling the valve guide holes and this is done in the jig shown in Fig. 5. The casting is again located with the two dowel holes previously referred to. The piece is then fastened in the jig with clamps at A, afterwards being slid along the track B until the index pin will enter a locating bushing in the base as shown. The 16 drills are guided through long bushings in the jig plate so that the holes produced will be perfectly straight and in the correct alignment and the size of the holes drilled is .745 inch. The locating pin C is then removed and the casting and jig moved along the track to a similar machine and located by means of a pin similar to C, and after substituting a correct jig plate the holes are reamed to ¾ inch.

Attention should be called to the convenience of the jigs used at this plant, the parts are easily located in them and also positively, employing the same locating medium, two dowels. And further, by means of the tracks and swinging type of tools, very little manual labor is called for on the part of the operator, merely sliding in the casting and revolving the jig to the correct position and then sliding them on the tracks under the machine. The valve chamber holes are next reamed out to 1½ inch, using a simple plate jig to guide the tool.

The holes for the studs to hold the manifolds are drilled as the next operation, and as this is a 16-valve type of engine, two intake and two exhaust for each piston, the manifolds are placed on each side of the cylinder. The jig used when drilling these stud holes is shown in Fig. 7. The casting is again located with the two dowel holes and fastened in the jig by means of four clamps as A, two on each side. The jig is then pushed under the machine by means of the tracks B until the jig plate will enter on the locating pins C, the jig and drilling plate are then in the correct location for the machining operation. Twelve 21/64 inch holes are then drilled in this side for its manifold. The jig plate is raised and the jig swung over 180 deg., being located with the index

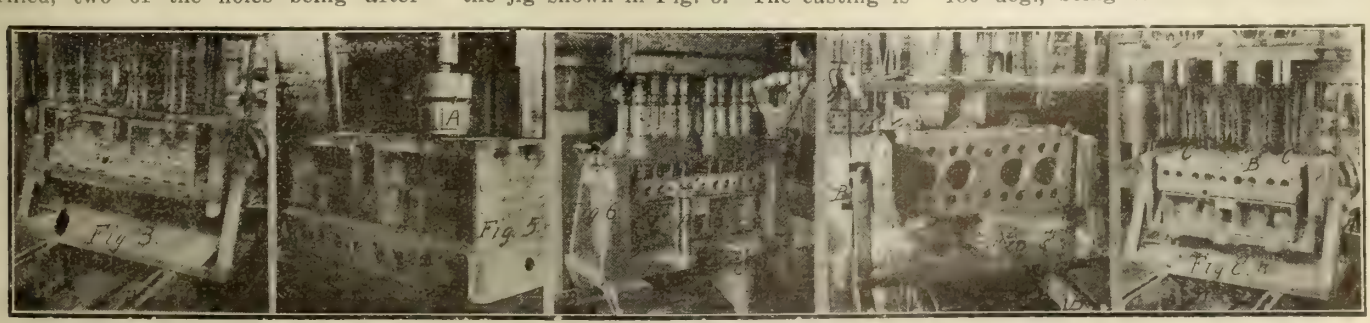


Fig. 3.—Drilling holes for crank case. Fig. 5.—Chamfering bore. Fig. 6—Drilling valve guide holes. Fig. 7—Drilling for stud holes. Fig. 8—Drilling stud holes for cylinder head.

pin and two locating bushings in the jig at the correct angle of rotation. The drilling operation is then repeated after the jig plate has been lowered into position, again determined with two more locating pins fitting in holes in the plate. A number of minor operations now follow such as tapping various holes, chamfering the valve guide holes and then the piston bores are ground to size.

The next work performed on the cylinder is with the jig shown in Fig. 7 and is that of drilling the stud holes used to hold on the head to the cylinder. The casting is located with the two dowel holes in the lower side and the revolving portion of the jig determined for position by means of the index pin A and bushing into which it fits. It will be noticed that this machine is also provided with tracks so the jig may be pushed into position with the least effort on the part of the man and in the quickest time. The jig plate B, which is used to guide the drills, is fastened into the proper position after which thirty-two 13/32 inch holes are drilled in the cylinder as shown by the half tone. A convenient medium for removing the jig plate is provided with the handles C, which are cast on the part, and is another example of the thought which has been placed in the designing of these tools and machining methods.

The casting is then given a hydraulic test of 35 lbs. pressure and if found satisfactory it is ready for inserting the studs or any other minor operations and is ready for the cylinder head.

Milling the Motor Heads

The first operation on the motor heads is milling the upper and lower surfaces. The fixture is an auxiliary attachment fastened to the main fixture used when milling the cylinder block. The head castings are placed in the fixtures, being located by means of stop screws at A, and held by the clamps B, two for each piece. Two 12-inch inserted tooth cutters are used to machine the surface C, after which the castings are reversed and the opposite face milled in a similar manner using the same cutters. By this method of employing auxiliary fixtures it is a very simple matter to change over the machine from milling the cylinder blocks to the operation on the heads. A hook bolt is provided in each fixture so that they may be placed on the machine easily, being then fastened down with bolts to the main fixtures.

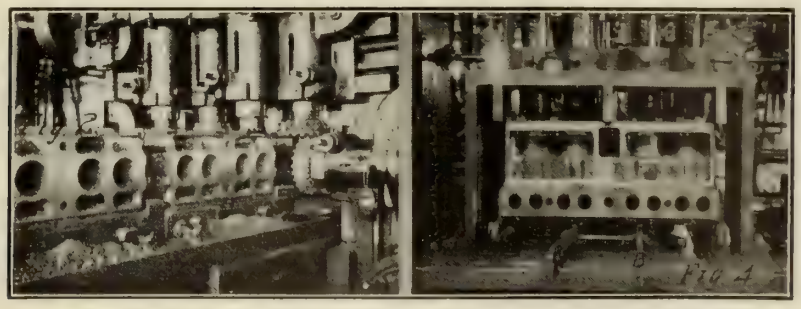

Fig. 2.—Milling twelve cylinders. Fig. 4.—Machining the bore.

Fig. 10.—Reaming for profiler. Fig. 11.—Profiling compression chamber.

The next operation is drilling the stud holes, and for this work a simple jig plate is used locating by the ends, and thirty-two 9/16 inch holes are drilled.

Profiling the Head

The casting is placed in the fixture shown in Fig. 10, which is used to ream a hole for the profiling operation. The casting is located in the sliding member of the tool by means of two dowels which fit in holes drilled in the previous jig. The casting A and sliding member are then pushed forward by means of the handle until the locating C will enter one of the position bushings placed in the movable part of the tool. The reamer D is fed down into the cored opening which is machined to 4½ inch diameter and 11/16 inch deep using a roughing and finish cutter in order to obtain the exact opening. The index pin is then withdrawn and the casting moved to the next position and the work repeated and so on until all four openings have been reamed. The result of this operation may be seen by referring to the openings at E. It will be observed that the reamer is provided with adjustable stop collars so that after these have been once correctly set all the holes machined will be similar in depth.

Fig. 11 shows the special fixture employed when profiling the compression chamber in the head. The casting is again located by means of dowels similar to the previous tool and it will be noticed that the same sliding sub-base is also employed here. Location of this sliding element is determined with the pin A which fits into locating bushings for the four positions to suit the correct locations of the machined openings. The milling cutter held and driven by the spindle is fed around to the correct outline which is determined by the guide C which the operator causes to follow the shape of the steel plate D. The shape obtained in this fixture by the method described may be seen by referring to the casting at E which shows a finished profiled chamber. It might be added that the milling machine table is locked during the profiling operation after it has been once correctly set, the four positions being determined with the locating medium described.

The spark plug holes are finally drilled, followed by the drilling of the water jacket holes. The jigs used are very simple in their construction. The head is now ready to assemble to the cylinder block and mounting in the receiving chassis.

HIGH PRICES AND BUSINESS

As representing the view that steel manufacturers entertain with reference to advanced fuel and labor costs and their effect upon general conditions in the U. S., the president of a large concern in the Pittsburgh district states:—

"It is evident that the country generally would be on a higher wage basis for some time to come. These higher costs in all lines, will, in my opinion, have a serious effect on business in two directions. First, exports will practically cease except in lines not produced in European countries. Second, the farmer will be unable to make his usual purchases on the present basis of costs even though crops are unusually good.

"The farmer cannot give four bushels of wheat for a day's wages and 12 or 15 bushels for a ton of coal and have much left to buy farm implements, automobiles and other articles requiring annually millions of tons of steel in their manufacture.

"The farmers are the largest consumers of manufactured products and their purchasing power is greatly impaired by such a situation. Evidently the price of farm products must go up or the prices of manufactured products come down before we can have the healthy basis of exchange necessary for general and permanent prosperity."

Less work at higher wages will be of little advantage to workers, says the steel maker. He adds that this "unfortunate possibility is due to the arbitrary readjustment to a normal basis in one or two important industries."

Precision grinding machines have a place in all manufacturing plants where accurate work is required.

Urge Canadians to Prepare for Trade Expansion

Commissioners From China and Scotland Describe Opportunities in Those Countries—Irish Government May Adopt Independent Policy—Showroom in Shanghai for Canadian Goods

DR. J. W. ROSS
Trade Commissioner to China

"ALMOST ANYTHING *can be sold in China. In the showroom which we are opening in China, sixty different Canadian lines will be displayed. China is an immense country and the upheavals that we hear of do not affect the reliability of those firms with whom business may be carried on."—Dr. J. W. Ross.*

"IT IS ADVISABLE *that Canadian firms be prepared to take advantage of these opportunities to trade with Ireland when they arise. Other countries are standing by, ready."—Major Gordon B. Johnson.*

MAJOR G. B. JOHNSON
Trade Commissioner to Scotland and Ireland

ADDRESSING a gathering of representatives of Canadian trade and technical newspapers recently, Dr. J. W. Ross and Major Gordon B. Johnson, Canadian trade commissioners from China and Ireland, discussed conditions and opportunities for the Canadian manufacturers in those countries.

Major Johnson pointed out that Ireland's position at the present time was one of economic dependence upon Great Britain but that the time would undoubtedly come, once internal troubles ceased and some evidence of stability returned, when there would be some national inclination toward greater independence in the matter of trade.

In 1919, ninety-one per cent. of the products of Ireland were shipped to British ports while 83% of the imports were from British sources or, in part, overseas goods transhipped through British ports by large houses in London, Liverpool or Glasgow. It was the speaker's opinion, and also that of leading men whom he had interviewed, that there was not going to be any violent change looking to trade independence from Great Britain. Through British brokers the marketing of overseas goods in Ireland is greatly facilitated. It was natural to suppose that once the Irish government became firmly established, ways and means of developing revenue would include that of entry tariff in which case direct business would result, rather than the double customs machinery necessary in trans-shipping through British houses.

Major Johnson stated that he had at least fifty enquiries for Canadian goods from Irish houses, with whom it would be a pleasure as well as safe and profitable to do business. These enquiries included such items as agricultural tools and machinery, for the south of Ireland was predominantly agricultural, asbestos fibre, aluminum ware, hardware, lead sheets and a great variety of canned goods and food stuffs. During the year 1919, Ireland's imports in iron and steel products including pipe and pipe fittings, amounted to $1,033,000.

The opinion was expressed that the action of the United States in raising her tariff barriers, would undoubtedly lead to restrictions in import trade, and to that extent would her export trade be impaired. The opportunity, therefore, was Canada's, for in this country were produced many lines similar to those in the United States, and these would find a ready demand overseas.

"WHEN Canadian Machinery and other trade and technical papers come into my office, I do not hoard them up. After I am through with them I pass them on to business firms who are most likely to be interested in Canadian affairs and in firms and products represented. In this way, quite a lot of very useful information finds distribution."—Dr. Ross, Trade Commissioner to China.

As to business conditions in Great Britain, including Scotland, there were many signs of substantial revival. The steel industry displayed renewed activity, as did the engineering field, but shipbuilding was still somewhat dormant. Naturally, this was an industry which followed, rather than preceded or paralleled, an industrial revival. As an example of conditions here earlier in the year, during the whole month of April only one small ship was turned out on the Clyde while a normal year's output was 400 ships of all kinds or eight ships per week. Since April, however, there had been some evidence of improvement.

One problem of Great Britain's trade was the unrest in Europe, and this was the explanation of a movement to establish more stable markets and to develop trade within the empire to a greater extent.

A list of imports into Scotland during 1919 showed large consumption of barley and other grains and foodstuffs such as produced in Canada.

Opportunity in China

Dr. Ross, trade commissioner for China, declared that almost anything could be sold in that country. It was a market of great potentiality, and one worth the serious attention of Canadian manufacturers. As an example he cited the fact that the last statistics showed importations from the Pacific coast of forty-two million board feet of lumber. There was a great market in China for newsprint, but it is not yet produced in Canada sufficiently light in weight to suit the trade. The Chinese required a sheet about 35 in. by 42 in. with a definite number of pounds to the ream. They do not see the advisability of purchasing a 50 lb. paper such as produced in Canada, when a 37 lb. paper such as secured in Scandinavian countries was satisfactory.

It was proposed by the Department to open showrooms in Shanghai for Canadian products and Dr. Ross stated that he proposed to have sixty Canadian lines on display there. There was a market for knitted goods, boots and shoes, silk hose, electric heaters, etc. As good roads in China were somewhat notable for their absence, the automobile trade had somewhat limited scope.

In an interview with Canadian Machinery, Dr. Ross stated that machine tool business in China was almost entirely in the hands of British firms, but that these had connections outside of Great

(Continued on page 41)

News From the Welding Field

Making the Welding Repair Shop Pay Its Way

Fluctuations in Volume of Business—Keep Man in Field Drumming Up Work—Taking on the Manufacture of Metal Specialties—Efficiency of Different Processes

ONE of the marked peculiarities of the business that comes to the door of the average welding shop is the tendency to suddenly vary in volume. One day the entire force will be on the jump from morning till evening, with part working overtime on the repair of an exceptionally heavy casting, which naturally calls for a prolonged and continuous performance of preheating and welding, and the very next day the boss finds himself puttering around the shop in search of jobs to keep the men busy. Quite naturally all repair work is wanted in a hurry, since a broken piece of machinery means a machine shop standing idle, so that there is a limit to the amount of work that can be carried over for the sake of having something for all the welders to do. Shall the welder sit down calmly when he has finished one repair and wait for something else to break? Not if he can help it. If it is a good sized shop there is probably a salesman out looking for machinery accident cases to hustle in for treatment, and if things refuse to break he investigates manufacturing processes to see if he can have parts of products sent to his shop to be assembled by welding.

Estimating on Work

A considerable volume of production welding for outside concerns has to be secured on each job in order to make the work profitable, because it requires practice to obtain sufficient speed on the work to justify making a price that will mean a saving to the manufacturer. Very often it is necessary to go to the trouble of making special jigs for holding the parts, or to the expense of having them made. Still the work is worth while if the price paid for it is enough to cover all the overhead with a slight margin of profit, for it can usually serve to keep the shop busy during the slack days.

When all other signs fail, that is when repair work inside and outside the shop falls off, and there is no demand for production work from other manufacturers, the welder still has a chance to keep busy by becoming a manufacturer himself. There is an almost unlimited number of metal specialities which can be turned out at small cost in a well-equipped welding shop, and for which a local demand can be found.

Manufacturing Possibilities

The metal can be obtained in sheets, rods, tubes, plates, etc., and cut to any desired pattern with a cutting torch, then welded together at odd moments, so that the cost of manufacturing is comparatively low. Some interesting work of this nature has been done, such as, auto axles, tanks, pans, screens, refrigeration equipment, house furnaces, depth bombs, aerial bombs, etc. The oxy-acetylene torch has scrapped many war vessels and guns. Welding equipment is indispensable to every large industrial plant for repair work, so as to enable them to quickly repair small breakdowns. The larger repairs are usually handed out to an outside shop to handle, because on large work special facilities, equipment, and organization is required.

New uses and applications of these processes are being found every day. The field offers unlimited opportunities to the workman and expert to show his initiative and skill, but let me put before you that the success of welding depends on:— The proper preparation of the work; the proper selection of process; the use of reliable equipment and supplies; the skill of the workman; the proper use of the preheating equipment before, during and after the welding; the necessary facilities to take care of the casting after heating; the necessary and proper skilled supervision of the expert.

The following is descriptive of the industry:—

Welder—The other day a big casting broke down in John Doe's Machine Works. Doe and the rest of his bunch all knew it was impossible to weld it.

Billy—Well, what became of it?

Welder—Why, they fooled me, I didn't know it was impossible to weld and they didn't tell me, so I went ahead and did the job O. K.

Where Gas Should be Used

The oxy-acetylene process is selected for bench work or the smaller castings

Extract from a paper read before a recent meeting of the Candian Welding Society by A. M. Barry, of the St. Lawrence Welding and General Engineering Works, Montreal.

Left—Manufacturing chip screens for pulp mills, by oxy-acetylene welding. ¾ x 3 in. mesh. 3-16 in. round iron rods welded at every intersection. Right—Gyratory crusher repaired by electric welding. Repairs made for ¼ the cost of new casting.

in steel and cast iron and always for the other metals such as, malleable iron, aluminum, brass, copper, platinum, tin, zinc, bronze, or bell metal, silver or gold. The oxy-acetylene and electric salesman of apparatus are constantly at war with each other on the merits of their respective apparatus, both claiming that they can do the job by their process cheaper and better than the other fellow. Experience goes to show that electric welding is selected for steel welding, principally on boiler repairs and steel tank manufacturing. In boiler repairs not because this weld is a better weld, (in fact according to my observation it is not as perfect a weld as the oxy-acetylene), but because the heat is more concentrated. While making repairs to boilers, which usually consist of building up of corroded or wasted places, building up leaky caulking edges, welding up of cracks and fire cracks; further trouble is not started by the loosening of rivets from the heat of welding which would be the case should oxy-acetylene be selected on account of the great radiation of heat during the progress of the job. By the electric welding process the heat is much more concentrated, therefore the work is nearly cold, while with oxy-acetylene process we have large sections white hot, with more metal red hot. If rivets or staybolts are in these sections we have rivets that are loose in the hole, the same arguments applying to staybolts.

Application of Thermit Welding

Principally in welding heavy sections, when broken, such as locomotive frames, steam-shovel parts, heavy frames, rolls, stone crusher parts, contractors' equipment, heavy crank shafts, shears, either in cast iron or steel, the Thermit process is adopted. Results in steel are to my mind always perfect. In cast iron a small percentage of failures and hard welds. The marine repairs by the Thermit processes usually consist of repairs to shafts, connecting rods, stern frames, rudder shoes, stem posts, rudder frames, anchors, and heavy davits. The Thermit process is also used in pipe and track welding to eliminate joints.

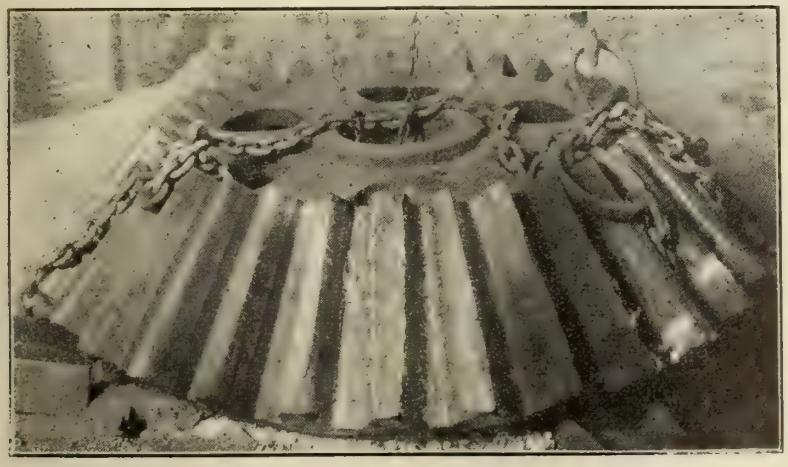
Electric welding consists of two processes, using two systems, metal electrode and carbon. The carbon is used principally in cutting steel, in welding, in building up metal where required, such as in defective steel castings. The metal electrode is also used in building up of corroded or wasted parts, welding up of cracks and fractures in boilers, tanks, and of course in the manufacturing of steel tanks, smokestacks, acid-stills, pressure vessels, vacuum tanks and equipment, also making good, worn parts in machinery, such as building up of shafting after wear to oversize, ready to be machined to full size. Electric welding of cast iron is usually done by first opening the fracture by chiselling a "V" then drilling and tapping in steel studs into the V leaving them about ⅛ in. high, then using a good Swedish iron electrode, which is generally 5/32 in. dia., filling up the "V" and heavily reinforcing when possible.

The Oxy-Acetylene Process

The oxy-acetylene process, to my mind, at least, is the only process by which all metals can be welded or any combination of metals. By its use it is possible to weld any broken part that is made of metal. Its usual application in a welding shop is to repair automobile parts, cylinders, frames, brackets, gears, shafting, (boiler tubes) crank cases, pipe and pipe fittings, intricate machinery parts (anything from artificial legs to marine boilers, from piping 40 ft. under ground to bells in church towers).

Oxy-welding is not a cheap repair process when working on small castings on account of the high cost of labor, gases, material, maintenance of equipment and unseen losses such as ends of rods, gas not accounted for, occasional idleness, defective work and the high overhead necessary. In manufacturing by oxy-acetylene the field is the same as above in electric process, with what I consider the additional advantage of the cutting of steel, which can be done by hand or machine. In flat surfaces, and heavy cuts, such as armored plates and ship plates, the oxy-graph is used, giving cuts that are smooth and accurate. By hand, ordinary cutting of plates, using a roller attachment gives good results up to 1 in. thickness

Failure and condemnation of welding is the direct result of welding equipment being placed in the hands of the unskilled and untrained workman, who with his unlimited nerve and irresponsibility undertakes, sometimes through force of circumstance, work utterly beyond the capacity of his equipment and skill. Result, a complete failure usually after considerable time and expense has been incurred taking out the broken part and replacing. This always creates a bad impression and unfortunately not the workman but the process is blamed.



Repairs made to large bevel gear, weighing approximately 6000 lbs., at plant of St. Lawrence Welding & Engineering Co., of Montreal. Repairs effected at a cost of about 1-6 that of a new gear. One new tooth built up and rim welded in three places.

URGE CANADIANS TO PREPARE

(Continued from page 39)

Britain. Manufacturing in iron and steel had to do with shipbuilding, production of cotton mill equipment, engines, etc., such industries being largely under British control.

The Chinese, Dr. Ross stated, were great readers and had their own papers, which were served with latest cables. They were quite as fully informed of happenings in the Near East as were Europe and America. One of the largest printing establishments in the world, called the Commercial Press, was owned and managed by Chinese. There were no trade or technical newspapers in China, the nearest approach to these being the Far Eastern Review, an English engineering periodical. In Shanghai there were a number of English newspapers. Every little port had its paper and there were a great many social and sporting sheets used to a certain extent for scouting or for purposes of propaganda.

Col. J. B. Maclean, who presided, pointed out that the Department of Trade and Commerce had a great amount of useful statistical information available to Canadian manufacturers if they would only take advantage of it. Under Hon. J. A. Robb the department was being developed, at last, along more businesslike lines and a broader policy was being observed in making useful information with reference to trade enquiries more easily available to manufacturers. There was, moreover, a keener sense of appreciation as to the co-operation possible through trade and technical newspapers.

During a brief discussion, it was suggested that business men returning from trips abroad might do a valuable service by broadcasting through the Department such information as they might consider valuable to business interests as a whole.

Practical Ideas From Practical Men

BALANCING A 3-FLOOR DRIVE

By W. F. Schaphorst

The vertical belt drive has been a hoodoo and perhaps always will be. About the only way such a drive can be run satisfactorily without keeping the belt too tight is by the aid of an idler,—and how some men preach against idlers! I am not opposed to idlers where they are necessary. They do not consume much power if properly designed, maintained and are kept clean. It has been shown that such idlers consume so little power that the loss is not traceable. This sketch illustrates an example where a single motor furnishes power for three floors, with no vertical belt. The principal feature of the drive is the almost perfect balance. It is laid out for a distribution of 100 horsepower to each floor, and with pulleys of equal size. The belt pull from each floor is the same. The angle between drives must be exactly 120 degrees. It is unfortunate that all three belts cannot run in the same plane, as the balance would then be perfect and there would be no thrust on the motor bearings. But with pulleys close together, and by using heavy belts, the thrust will be very small. This arrangement permits 98 per cent. efficiency (or very close to it.)

On the horizontal drive is shown an idler on the underside, which is the slack side. This idler may or may not be used, as it depends mostly upon the pulley sizes, generally the idler is placed close to the small pulley, but in this case it is used to hold up the belt and keep it from rubbing against an obstruction. The matter of balance is always worthy of consideration and perhaps it would pay to look the drivers over and correct the balance if need be. This can sometimes be done by merely shifting a bearing.

USING THE TOOLS OF ANOTHER TRADE

By D. A. Hampson

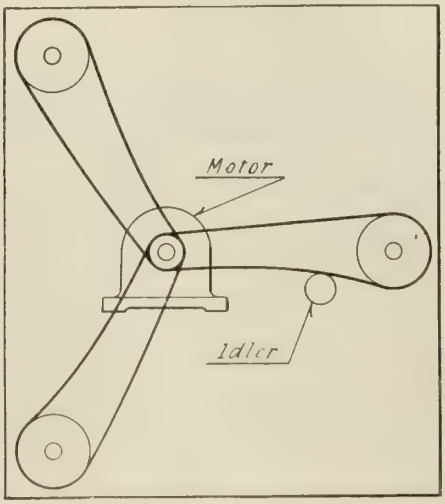
Two cases have recently come to notice where progressive machine shops adopted devices peculiar to the printing business for the purpose of securing greater efficiency in production work. They are illustrated herewith. In order to best appreciate these set-ups, it will be worth while to review the conditions under which a printer works.

A printer's "form" consists of a rectangular metal frame, or "chase," inside of which are placed the type, machine cast work, cuts, etc. This interior "matter" is squeezed against itself by means of various locking devices, the reaction of which is taken against the surrounding chase. When it is considered that even a small form, say 28 in. x 40 in., contains thousands of pieces of type and that not one of these must be so loose as to fall out when the form is lifted, the skill of the printer may be appreciated.

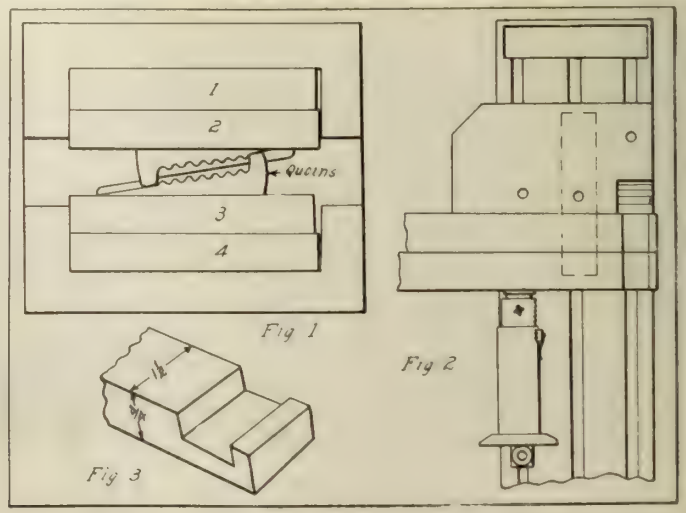
We in the machine trade would call the process of fastening the type a "clamping" process but the printer speaks of it as "locking up" and he knows the different devices used as "locks." One of the commonest locks consists of two wedge shaped pieces of steel or malleable iron called "quoins." These have teeth on their inside faces by which the opposing halves are caused to open or close using a T shaped tool with the business end shaped like a cross and this end slides the halves in opposite directions. To see a printer drop in half a dozen quoins and lock up a big form with his key in a few seconds is a lesson in speed. Long before time study came into the machine shop, the printers had their cost systems which analyzed every movement of the hands and feet in the effort to provide more efficient means of meeting the competition which is theirs.

Next to speed and results, the one thing that impresses the machinist is the fact that there is no head room on printers' work. All type is .918 in. high—that is the printing height for everything—and consequently the other parts of the form have to be much lower in order not to run any risk of printing—in practice, heights of 5/8, 11/16, and 3/4 inch are used, depending on the class of work. It must be seen that any lock only 5/8 high which can hold a big page of type and not tip it has passed the acid test of time. All parts of a form have to be kept flat because printing on a spring surface and the suction of inky rollers would soon work it loose on the press. The proven efficiency of printers' locks no doubt had much to do with their selection in the cases to follow. A positive lock, quick acting, and of little vertical height was essential.

Several thousand rough pieces of Stellite were to be ground to an exact 5/8 in. square to fit a special tool holder. The work was to be done on a Blanchard surface grinder with the well known round magnetic table. Naturally Stellite cannot be held on the face of a magnetic chuck. Fig. 1 shows a plan view of the fixture that was made up. This fixture was held on the magnetic chuck and the work pieces were to be clamped mechanically in its upper face. It was for the latter purpose that the printers' lock was used—a clamping scheme that would be quick and sensitive was required. Two of the Stellite bars were placed against the rib on each side and the quoins dropped between them. A twist of the wrist (on the quoin key) and the four pieces were held as securely as could be wished. This



Balancing a three floor drive.



Using tools of another trade.

application might well be duplicated on other work where a low clamp, accessible from the top is desired.

Fig. 2 shows a miling machine job. Drawn steel bars ¾ x 1½ are notched half way through on each end. In length, the bars run from two to six feet. The cuts have to be made very accurately, both as to depth and squareness, and to that end the bars are clamped directly to the miller table and against a low rib having its face square with the tongue that fits one of the T-slots.

Sometimes one bar is to be cut and at other times there are as many as a dozen. To keep the cost down it is necessary to have a rig that may be quickly set up, produce work whose accuracy is undoubted, and with which the parts may be handled quickly. By clamping to the table itself, and against the rib, these results are secured. A clamp reaches over from the front and holds one or two bars, as the case may be—this allows a maximum of room for the arbor and allows the table to be run back far enough at the end of the cut to make it convenient to handle the bars and clean chips out.

Making the notch at one cut and at a modern production rate creates more or less vibration and some means has to be provided to keep the bars against the rib, otherwise the cuts would be a few thousandths out of square and the bars spoiled. A printers' device is used for this purpose and seems to be the ideal thing.

In this case it is a device known as the "Slauson cylinder press lock" and was developed for locking chases on the flat beds of cylinder presses. Very often a form is made up for cylinder press work in a chase much smaller than the press bed—the lock used, therefore, must have a wide range or else a lot of filler material used, which causes the form to work up. This lock is made of two telescoping pieces of steel tubing and has two expansion adjustments—one being through teeth on the edge of the inner tube which engage a latch and the other through a cam expansion device at the end which gives a powerful squeeze through a limited range.

On this bar notching job the workman places his bars against the rib, clamps them lightly and then forces them into close contact by means of the lock. It is an absolute guarantee against working out of square. A short bolt, drawn down on the table itself and set about a foot away from the work, serves as the stop against which the lock is placed. Again, the single twist of the wrist actually locks after the tubes have been pulled through the larger increment — another twist loosens the work when the cut is finished. Those with clamping problems where the height is limited or quick action desired or where clamps must be installed in narrow spaces will do well to investigate the devices which trained men have developed for printers.

KEEPING THINGS HANDY

By Harry Moore

There is an old saying: "A place for everything and everything in its place," but like a good many of these wise saws this is much easier to say than to carry out. Machine shops are, as a rule, no less tidy than shops of other kinds, but it will hardly be denied that such ideal conditions as indicated by this maxim, are next to impossible in actual practice. Without, however, striving to attain to such an exalted state of orderliness, it is possible to make things run more smoothly by the adoption of simple methods for keeping frequently used machine shop articles in definite places. Every one has ideas as to how this should be done; one shop, for instance, keeps certain small nuts in tin cans, another strings them on a length of cord, another on wires, and so on, each with its own method which may or may not be the best for its own particular use.

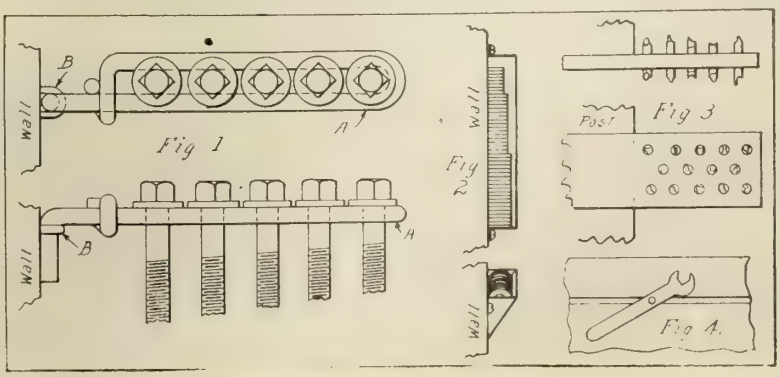
Herewith are a few simple holders used for keeping commonly used machine shop parts in handy positions. The bolt holder shown at Fig. 1 is used to keep a few bolts of varied lengths, together with nuts that fit, in a position where they can be easily removed, but where they cannot drop out or become mixed up with others. The idea of a holder of this kind is that certain bolts and nuts can be kept together with the assurance that each nut is a proper fit on the bolt upon which it is placed and that the length of each bolt is in full view. In this way much wild confusion is avoided when rush jobs come along; there is no searching for suitable bolts and neither is there the otherwise all too frequent occurrence of nuts jamming on the bolts when a set-up is being made. The only material required for this holder is a length of rod A about ⅜ in. dia. This is bent to the shape clearly shown in the drawing and when in place it swivels on a staple B driven into the wall or post, so that it can be swung out when placing or removing bolts and laid flat to the wall, out of the way, when not required.

The washer holder shown at Fig. 2 can be made in quick time out of a strip of sheet metal and when attached to the wall or any convenient place adjacent to the machine it forms quite a handy receptacle for washers of varied thicknesses such as are generally used for packing up purposes. By using a holder like this any washer selected can be removed without disturbing the others, and by placing it in an angular position as shown, the contents are always in neat order, as they naturally slide down and fill the gap made when some are removed. When fixed in place the holder forms a half vee by reason of the ends being bent to an angular shape as at A. A hole drilled at each end takes the screws used to attach the holder to the wall, post, or bench as the case might be.

The tool bit holder shown at Fig. 3 was recently noticed in a small repair shop and for simplicity it would be hard to beat. This is merely a piece of hardwood board A, drilled through at one end to take the bits, and screwed to the wall at the other. The originater of the idea had the board fixed to a post where it projected over the lathe at about his own height, so that it was entirely out of the way yet both ends of the tool bits could be clearly seen. This is a decided advantage over many kinds of toolholders where the operator is compelled to lift each tool out in order to examine the shape at the hidden end, when the kind he requires at the moment is not in view. By using hardwood and drilling the holes a size suitable to take the tool bits snugly, a good permanent tool holder is secured.

Fig. 4 shows a wrench holder. There is always one wrench which is used around a machine more or less continuously and much time and annoyance is saved if a definite place is made where it can be kept safe from wandering. The device consisted of a sawed off tee bolt tapped for a set screw. This can be placed in any handy out of the way position in the tee slot and tightened in place with the screw. By drilling a hole in some part of the wrench it can be placed over the screw head and thus be effectually prevented from rattling off the machine under vibration.

When a grinding wheel is working properly, the abrasive grain in the wheel may be considered as cutting small chips from the work, and the surface of the work as cutting or wearing away the bond of the wheel.

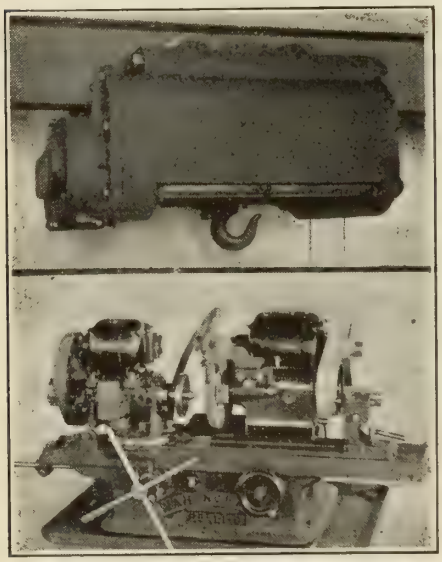


Devices for keeping things handy.

New Things in Shop Equipment

SHORT HEAD-ROOM HOIST

A special hoist for use on mono-rail systems has been placed on the market recently. Where a hoist is to be used in a room with a low ceiling, or in a room where a definite head-room must be maintained for safety sake, or where material of large size is to be lifted or transferred from one place to another, it is frequently an advantage to have a hoist that occupies small space with comparatively long lift. In the hoist here illustrated all the shafts are made of high carbon steel, heat-treated and ground to size, and fitted with roller bearings of the Hyatt high duty type. Accurately machine cut gears of forged steel are used throughout. Pinions are of high carbon steel, heat treated. The drum is of simple design and of rigid construction; grooves are accurately machined and coil the rope in a single layer. The controller is of a new type, built especially for hoist service. The motor is fully enclosed and equipped with ball bearings. The automatic mechanical lowering brake runs in an oil bath, and is provided to control the lowering speed. It is of the screw and disc type, geared to the intermediate shaft and having three discs. The automatic holding brake works on a pulley mounted on the hoisting motor shaft proper, and is asbestos lined. It is operated by a cam on the controller shaft. The circuit is broken at the upper limit of travel. Two or four-rope blocks are provided; blocks are steel yoked and carry a forged steel hook, working on a swivel. All gears operate in a bath of oil and automatically "splash lubricate" all main bearings. These hoists are made by the Standard Electric Crane and Hoist Co., Philadelphia, Pa.



Upper—Short head-room hoist.
Lower—Re-li-o tool room unit.

RE-LI-O TOOL ROOM UNIT

A small universal grinding machine of interesting design has been placed on the market recently. The work-head has a graduate swivel base with a locating pin for 30 to 45 deg., and a central lever binder. The work-head spindle has large diameter taper bearings, with take-up for wear, by means of a hardened thrust collar and a ring nut. The tail stock has cross-adjustment for off-set or alignment as required. A diamond wheel-truing tool is mounted on the inner side of the tail-stock. An adjustable limiting stop screw with lock-nut is attached to the head end of the table. The wheel head, lathe tool block and the cross slide are cast in one piece and machined as a single unit—thus insuring rigidity and freedom from chatter. Wheel spindle runs in ball bearings with ample provision for lubrication, by means of an oil reservoir cast in the wheel head. The internal grinding arbor can be mounted on the end of the regular external wheel spindle. The lathe tool-holder and its cutter are mounted at the front end of the cross slide which converts the machine into a serviceable lathe for straight or taper work. The cross-feed screw is operated by a hand-wheel with dial graduations to read in thousandths of an inch. Machine will swing 8 in. over table. Work 12 in. long can be carried between centres. Table has a travel of 10½ in. Cross feed movement 6½ in. Table has area of 36 x 6½ in. Floor space required, 38 in. x 30½ in. Weight approximately 350 lbs. These tools are made by the Van Norman Machine Tool Co., Springfield Mass.

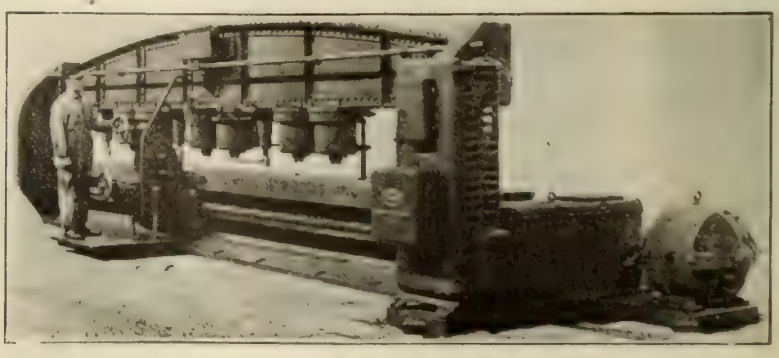
IMPROVED PLATE PLANER

An improved type of heavy plate planer has been placed on the market recently. The tool carriage is attached to the front vertical side of the bed, and is guided in same by square shears. It is bearing supports, which will permit the secured top and bottom by removable carriage to be taken from the bed at any part of its length. The bearing surfaces are provided with taper gibs for taking up wear. Two relieving tool holder slides are mounted on a standard and have simultaneous vertical adjustment by means of a screw and hand wheel, and horizontal adjustment to the standard through screw and hand wheel. Both tool slides are provided with swiveling feature to allow the planing of bevels. The drive screw is supported in a trough with an oil channel of sufficient depth to cover the full depth of the thread with oil. Roller bearings are provided to take the end thrust of the screw.

The pneumatic jacks are of the two-way type, i.e., air is admitted in the top for clamping the plate, and for unclamping the air is admitted at the bottom. The carriage is reversed automatically at any desired position by contact with stops adjustable on the shifter rod. The operator can start, stop, or reverse the carriage by manipulating this shifter rod by hand. This can be done with very little effort on the part of the operator. The main driving gears are enclosed in a box, and dip in oil. The motor is controlled by a master switch attached to the shifter rod, and an enclosed panel with forward, reverse, accelerating, and dynamic brake contactor. A push button is mounted on the right hand housing, so that the machine may be started and stopped without manipulating the shifter rod. The cutting speeds range from 20 to 40 in. per minute. These planers are manufactured by the Niles-Bement-Pond Co., New York.

GROUND-FORM GEAR CUTTERS

Ground-Form gear cutters which are ground on the tooth form, have recently been introduced to the trade. The grinding process corrects all hardening distortions, giving each tooth great accuracy of form and aligning all teeth with the hole in the cutter. As the tooth form of these cutters is accurate to very close limits, the tooth spaces of the gears cut will be correspondingly accurate. The alignment of the cutter



New design of heavy plate planer.

teeth secured by grinding makes it additionally certain that the spaces between the gear teeth will be true to form. Grinding of the tooth form also gives a positive method of controlling the form of different cutters and securing duplicates. This ability to secure duplicate cutters is of great importance to the manufacturer of gears in quantity who is seeking both accuracy and uniformity. The introduction of ground-

Ground form gear cutter.

form cutters solves a difficult problem confronting gear makers to-day—the duplication of accuracy.

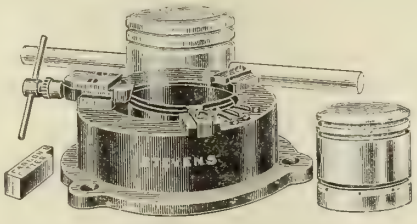
The correction of hardening distortions by grinding aligns all the teeth. This gives ground-form gear cutters a free cutting action largely due to the fact that no tooth or group of teeth does the major part of the work; each tooth does its share. The keener cutting edges formed by the conjunction of the ground surfaces of the teeth add to this freer cutting action and give the cutters a capacity for increasing production which in actual test has proved to be surprisingly great. Not only has a faster feed been used with these cutters but they have cut more gears between resharpenings. This ability of ground-form cutters to wear longer is due to several factors. As the work of cutting is evenly distributed among all the teeth, the resulting heat is not confined to any one portion of the cutter. This removes one of the commonest causes of cutter wear-localized heating. Another factor which adds to the life of these special cutters is that grinding of the form gives the teeth a positive clearance, eliminating "rubbing" of the form back of the cutting edge. These cutters are made by the Brown & Sharpe Mfg. Co., Providence, R. I.

TESTING AND RECORDING MACHINE

The illustration herewith shows a machine that has been developed for testing and recording the efficiency of pneumatic hammers. The hammer to be tested is clamped in the machine and the impact of each blow is transmitted through a column of oil to a diaphragm which communicates the vibrations to a magnifying lever, which records the blows upon paper tape operated by a recording instrument that registers the number of blows each second of time, or any number of seconds continuous run. The length of the vertical lines in the graphic record sheets give the power of the blow; the number of the vertical lines the speed. The air consumption is accurately measured by a water-displacement meter which is connected to the hammer, and registers the air used. By running a series of tests of different hammers of the same size, and selecting the record having greatest length of power line, we obtain a master record to which all tools must conform before they are shipped out. This machine eliminates the human element, substituting accuracy in place of guess work, giving dependable data on the effective work done by a hammer. This machine is manufactured by the Cleveland Pneumatic Tool Co., Cleveland, Ohio.

PISTON OIL-GROOVING TOOL

To counteract oil-pumping pistons, it has become the widespread practice to put an oil-groove on the piston and also to drill oil-return holes in the groove. The tool here shown has been designed to cut and chamfer the oil-groove in pistons and likewise to serve as a jig

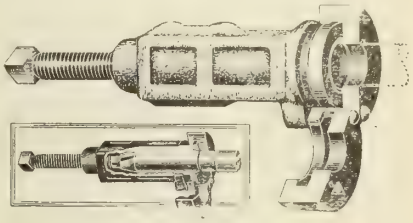


Piston oil-groove tool.

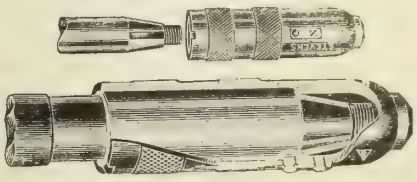
for drilling the oil-return holes. This tool chamfers the lower edge of any groove in the piston at exactly the correct angle. The cutter is made of high grade tool steel and has proper clearance to obtain a clean, smooth cut. The feed screw has a stop to prevent an accidentally deep cut. When the tool is fastened to the bench, the piston is inserted, disassembled, but when it is clamped vertically in a vise, the piston may be inserted with the connecting rod turned by passing the bar through the connecting rod bearings. Burnt carbon deposit is removed from the bottom of the ring groove by using a flat cutter in place of chamfering cutter. One of the steel jaws is designed as a jig for drilling the holes. Graduations on the face of the tool allow of uniform spacing of holes. It is claimed that the method will cure the most persistent case of oil pumping. These tools are made by Stevens and Co., New York.

PULLER AND DRIVER

It is very often a difficult task to remove an automatic drive shaft sleeve with ordinary tools. The tool here shown is claimed to make this job an easy one. It is equipped with steel jaws that completely surround the sleeve, so that any required pressure can be applied through the large steel screw without injury to either sleeve or shaft. The inside is machined to a close fit on the sleeve to prevent the tool from springing out of line or jumping off under



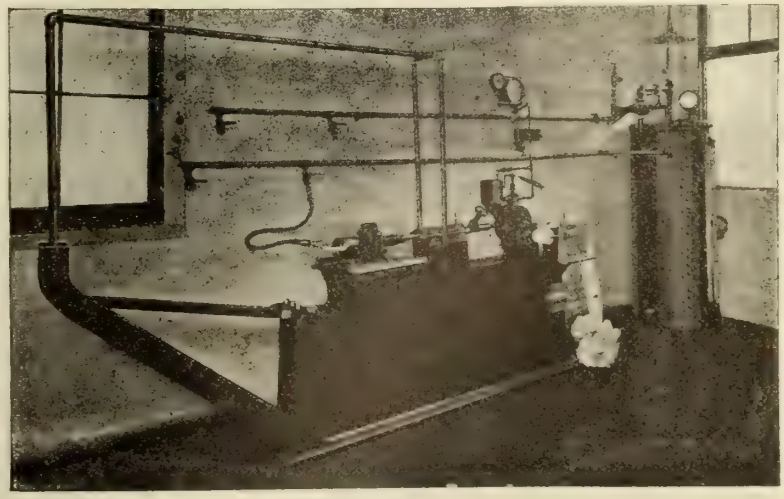
Drive shaft sleeve puller.



Drive shaft sleeve driver.

pressure. The square bosses on the sides are for securing the tool in a vise.

The driver has a novel feature, as it is provided with a "sight," consisting of a special notch and pin, which insures the proper alignment of the keyway slots as the sleeve is driven into place. The sleeve is driven with safety. These tools are the product of Stevens and Co., New York.



Testing and recording machine.

Canada's Export Opportunity

DURING the next two months, business men will have an opportunity to discuss export affairs with two Canadian Trade Commissioners, Dr. Ross for China, and Major Gordon B. Johnson for Scotland and Ireland. In statements which they have made it is evident that important markets await development in a larger way than heretofore by Canadian manufacturers. The opportunity seems all the more real because of the curtailment that must result in trade with the United States because of the high tariff barrier which that country is raising in protection of home industry and in more intensive development of their home market. Canadian manufacturing processes follow those of our neighbors to the south very closely, and in appreciation of export opportunities in Canada the number of branch factories here is steadily increasing. Products should, therefore, be such as to meet the requirements of a trade that may be diverted in this direction.

There is no doubt but that trade commissioners are fully aware of these conditions, and while making much valuable export information available, are further entitled to the confidence and co-operation of the manufacturer who may be in possession of facts and figures that may be broadcasted with general benefit to Canadian industry. At the same time there is much valuable material in the shape of statistics, and detailed information for exporters and importers available in the department to manufacturers. There seems to be a real opportunity for the practical application of this material.

Industry Versus Small Politics

IT IS CHARGED by a manufacturing concern in one of the larger Canadian cities that they have had some difficulty in developing a working force by the so-called paternalism of local politicians within the board of aldermen and other municipal bodies. It is pointed out that these men adopt an attitude which is almost equivalent to interference with the work of organization and that the feeling among workmen that friends at court are working in this behalf, looking to a snap on the city payroll, even if only temporary in character, tends to retard the building up of a desirable permanent staff. In short, it is evident that activity in the vote market demoralizes, in not a few cases, any influence looking toward industrial co-operation.

There are men, it is stated, who have, on busy occasions, refused to work overtime because of an attitude of independence encouraged by the promises of a ward or lodge politician. In some cases men who have been induced to work overtime, have failed to report for duty the following day and it actually developed later had applied for the easy unemployment assistance doled out by the city though still having a job available to them.

It is possible to imagine how conditions such as these might disturb the esprit de corps desirable in connection with a large industry especially when the wage rate paid by the city for common labor is considerably higher than that available in private concerns. Labor is entitled to everything to which it is legitimately entitled, but surely it is a misguided sense of public importance which causes a local politician to become a busybody to the detriment of industrial affairs. It is this kind of thing that unscrupulous ambition breeds upon. Some criticism may be directed also toward a municipal system which pays, out of public funds, a higher wage rate for ordinary labor than many taxpayers are able to obtain for harder and more intelligent work elsewhere.

Develop Canadian Ore Industry

GROWING out of the feeling of dependence, if not of helplessness that emerges from experiences in coal strikes, it would not be surprising if any movement looking to development of the country's natural resources in raw materials became more insistent. Some such feeling predominated at a recent meeting of men interested in iron ore mining and the blast furnace industry and if nothing else were wanted but statistics, there is a strong case in favor of an exclusively Canadian industry. During the past thirteen years, it was pointed out, Canada had imported iron and steel products to the value of $1,235,000,000, all of which should have been produced in Canada. For her 40,000 miles of railway, the country should produce seven million tons of steel instead of two million. If that were done, there would be one billion dollars invested in the mines and plants and thirty million tons of iron ore, coal, and limestone handled annually. The produce would be worth six hundred million dollars. Employees would receive one hundred and fifteen millions; the government, fourteen millions; railways, eight millions; municipalities, eight millions in taxes, besides about eleven millions for the use of public utilities. These statistics were emphasized as setting definitely the question of markets and of the sufficiency of ores in Canadian ranges for future demand.

The situation, however, promises no improvement until the governments see fit to assist in the mining of the ore by way of bounty or in making power available at nominal rates, or both. Existing steel companies are sympathetic, and have spent a great deal of money in investigation work on the different ranges and ore bodies and authoritative opinion emphasizes the fact that problems confronting the Canadian industry are no more serious than those which have been surmounted in the United States.

Market not so Ambitious but Prices are Firm

Mills Urge Advance Buying and Premiums Disappear—Quotations Indicate Stability But Levels Maintained—Canadian Markets Fairly Active—Reluctant to Advance Prices—Relief in Pig Iron

STEEL CO. BLOWS IN 500-TON FURNACE

AN AVERAGE advance of $9 a ton, or about one-half as much again as that of the great market movements of 1909 and 1912 has marked the movement in iron and steel during the past six months. According to Pittsburgh advices, this advance includes all steel products. Comes the inevitable reversal, probably due to increased production since the coal strike settlement, coupled with the fact that buyers are drawing upon stocks accumulated in anticipation of interrupted delivery. Car shortage is being stressed as a reason for orders, but the condition to-day shows improved deliveries on old orders, premiums for early shipment fading out, and there is some feeling that prices on placing business may have to decline. Against this, the fact must be considered that storage of products on a large scale is necessitated and this must add to costs. Basic prices are decidedly firm. Wire products have advanced. Shapes, bars and plates are very firm at $2.00 to $2.25. In Toronto markets the price is $3.25 to $3.40, and there are those who maintain that this does not represent a sufficient spread as between Pittsburgh mill and Toronto warehouse, or say, between the Hamilton basic price of $2.70 and Toronto warehouse. However, it is characteristic of the Toronto market to be quite conservative in the matter of price advances. Conditions in the past three months have necessitated an advance on bars, for example, of from 35 to 50 cents per hundred pounds. Sheet demand has been strong and here, too, advances have been frequent.

Relief in the coal situation is improving somewhat, and the Steel Company of Canada finds it now possible to blow in one of its 500-ton furnaces on basic pig. This will help reassure Ontario foundries who were running short. Toronto price for pig iron still stands at $39.30 for spot, while Montreal quotes $35 at dock for Summerlee Scotch pig. There have never been large tonnages of this available. During an acute period small quantities of this iron made its appearance in Western Ontario.

September's record in the Canadian iron and steel business was a fair record, though by no means as spectacular as might be expected as reflecting the movement in the American market. Railroads have been a strong factor there, while here, apart from the purchase by National lines, of machine tools for Eastern and Western shops, there has not been any notable buying movement. The scramble by the American lines to add to their equipment is already seen to be a trifle belated to meet present emergencies, and it is held that there is danger of a like problem developing in Canadian demand for rolling stock.

Machine tool demand is reported as showing some slight improvement in the past month's record. Shop and mill supplies have been active, and in this connection it is pointed out that the mining regions of the north are becoming an increasingly important market.

Toronto

October 4

WITH coal and rail strikes a thing of the past, the iron and steel market here is confronted by two conditions. One of these has to do with shipments from American sources which are still beset with difficulty, and the other is the time-honored law of supply and demand which always demonstrates its rigidity most positively when speculative tendencies obtain any headway. Such speculation is said to be already in evidence, reflected by the feeling that prices should shortly become easier. It is an unreasonable expectation in view of the present tendency of the market toward a very firm price attitude behind which there are statistics to prove that steel production has been conducted on a somewhat threadbare basis and that advancing wage and other costs absolutely prohibit price recessions for some months—say until the first quarter of 1923.

There are those who contend that Toronto market has itself to blame. Opposite influences are at work which contribute to instability, but which are expected, nevertheless, to promote buying. The situation may be best illustrated by the experience of a buyer who had an order up his sleeve for a fair sized order of merchant bars. With Canadian mill prices at $2.70, and Buffalo warehouse prices at $3.10, he was advised by a steel man that he would probably find that the reselling price was around $3.70, or a spread of about 60 cents over Buffalo and about $1.65 over Pittsburgh. The quotation he actually received was $3.20. He concluded that the Toronto market must be either fairly well supplied with low priced bars, or that competition was maintaining very low levels in spite of upward trends on the American markets. On the one hand there are those who contend that business does not warrant an advance; on the other there are those who declare that Toronto prices have never been in line with those of the American market and that selling has been on a basis most favorable to the buyer. At that, during the past three months, the advance in bar prices has advanced 30 to 50 cents per hundred.

Iron and Steel.—Price ranges on iron and steel bars continue at $3.25 to $3.40, with the bulk of the business being done at the first-named figure. It is claimed in some quarters that an advance is in order, but there is an undertone of reluctance. Business has been coming along steadily, but during the past week is reported to have been somewhat spotty. September, in bulk, was a fair month, but there is yet a lack of that activity which has characterized American business. Dealers declare that such a movement does not generally develop on the other side without some definite reflection here. There is confidence that it will come and in the meantime, there are dealers who declare that they will not be guilty of premature action that may discourage it. However, necessity does not stand on sentiment and the market at present may be described as halting between two influences—advancing or maintaining present levels. Certainly, there will be no declines. Sheet prices continue firm. An advance of $2 per ton on galvanized was recently announced and reflects general market trend. Here, too, the feeling seems to be that restricted markets cannot always afford to follow too closely the movements of one many times larger, and the attitude on price changes is inclined to be conservative. Current prices:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 75

Pig Iron Markets, so far as supply is concerned, are somewhat easier as coal becomes available. Steel Company of Canada have blown in a 500-ton furnace after an activity extending from middle of July. Spot quotations are at $39.30. Coal supplies for this production seem assured, and as the situation improves, the output will increase. Port Colborne furnaces are still out. Buffalo price is at $35. Small quantities of Scotch pig iron have made their appearance in Western Ontario, and a Galt buyer declares he bought some of this at a better price than any available from local furnaces. His purchase may have been made at a time when British pig was at a lower level than $35 dock Montreal, and when so-

called local furnaces were practically out of the market at any price. Improvement in the production of American furnaces is such that something like a war is expected in ousting foreign pig. For example, Scotch pig is quoted $30 to $33, c. i. f. Boston, and Belgian and French $26.50 to $28, c. i. f. Boston. Pennsylvania interests are quoting $35.65 delivered New England. Montreal is quoting Summerlee Scotch at $35 dock.

Scrap metal markets continue inactive, although the general undertone is declared to be good. There has been some little demand for non-ferrous materials. This may indicate that brass foundries are busy, but there has not been, recently, any work of big dimensions in this field. Dealers' average buying prices follow:

Copper, light, per 100 lbs	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Non-ferrous metals while recently subject to influences that make for activity, indicate no important movement on this market. London quotes tin prices as higher, in keeping with general metal lists; the copper market is firm, and New York reports large French and German business, electrolytic being quoted at 14 cents; lead markets are also showing strength; New York is quoting $6.35 to $6.40 by leading interests and $6.60 by the outsiders. Levels are high and buyers inclined to be conservative. Toronto prices:

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	36 00
Lead	7 00
Spelter	8 50
Antimony	8 50
Aluminum	23 00

Machine tool business is spasmodic. No one week may be taken as a hint as to the record of that following. Some good sales were made last month, including lists issued by the National railways for Eastern and Western shops. One dealer reports the sale of three turret lathes. Another had reason for jubilation in a list of supplies amounting to about $2,000, which included six 3-ton chain blocks. These were for a bridge-building outfit. Business from Northern mining camps is good and compris s much heavy mill equipment and supplies. A month's business nowadays is somewhat miscellaneous in character but indicates improvement.

Toronto purchasing agents returning from Pittsburgh district expresses the opinion that the steel and iron industry may find that it has gone after high prices too vigorously in order to cover losses that occurred during end of 1921 and beginning of 1922, and that some tendency toward conservative buying may be looked for. Nevertheless, markets are decidedly firm, although deliveries are badly handicapped. The opinion is expressed that price recessions may not develop until the first quarter 1923.

Montreal

October 4

TRADING in the iron and steel lines continues to gradually increase in spite of the difficulty of getting deliveries from the mills. September figures are very satisfactory indeed, and will be, as intimated last week, at least ten per cent. in advance of the figures for August. This statement is equivalent to saying that September was the best month of the year. British pig is being marketed more freely of late, and the risk of an acute shortage is past, for the time being. Machine tools continue dull, but the supply business shows that conditions are improving. The non-ferrous metals are rather quiet and quotations steady. The scrap markets are still fairly active with quotations tending to firmness.

Iron and Steel.—Steel and iron products are moving well locally. Prices have not been changed during the week, but it is generally felt that quotations will not be advanced, as the acuteness of the strike situation has been passed, and it was this factor that was responsible for a measure of the recent advances. Merchant bars are only moving fairly well, but all other lines have shown decided improvements during the week. One jobber carried a heavy stock of plates all spring and summer, but has been able to dispose of them recently, and is having more or less difficulty in replacing them as deliveries are rather distant. British plates and sheets are being marketed largely by the local jobbers. Sheets are beginning to feel the seasonal fall movement, and all varieties are called for. Structural steel from the outside towns seems to be in good demand also. Tire steel, band steel, spring steel, sleigh shoe steel, etc., are lines that are moving well. Miscellaneous small steel products are also experiencing a heavier movement. Already the jobbers feel that October and November will set new high levels for the year. Local quotations are as follows:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	3 40
Sheets, black, No. 28	4 40
Sheets, blue ann., No. 10	4 05
Canada plates, dull, 52 sheets	5 50
Canada Plates, all bright	7 00
Galvanized Sheets, No. 28	6 50

Pig Iron.—Canadian producers are more or less definitely off the market as all local quotations have been withdrawn. Stocks of Summerlee are very low indeed, and prospects of their being replenished at an early date are remote. Carron and Middlesboro have been active. One jobber has sold over 2,500 tons in the last few weeks. Quotations on British iron are $35, car load lots on docks Montreal. The nominal quotation on Canadian iron is $40.80 on tracks Montreal. The present indication is that British iron will supply the local needs until the close of navigation. Local quotations are:

Algoma, No. 1, car lots on tracks, nominal quotation	40 80	....
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	42 50	....

Machine Tools and Shop Supplies.—Machine tool markets are very quiet and there is very little indication that there will be any great or permanent improvement for some time to come. Among the few sales reported it is noted that woodworking tools appear to be moving a little better than iron-working tools. Supplies continue to move well. There has been a tendency toward stiffness in quotations, which has been reflected in somewhat larger specifications in several instances.

Non-ferrous Metals.—Copper quotations have not changed during the week but reports from London indicate that tin has advanced, and in sympathy with the movement, quotations have locally advanced a half a cent a pound. Spelter also advanced a quarter of a cent, while lead sagged off a quarter of a cent. Lead has been very inactive for the past week. Quotations on antimony and aluminum remained stationary. Business has been very fair during the week. Orders have been small but they have been numerous and well scattered. Local quotations are as follows:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	36 00
Lead	7 25
Spelter	9 00
Antimony	6 75
Aluminum	22 00

Scrap Metals.—An activity is noticeable in the ferrous scrap metals owing to the scarcity of pig iron and steel. Quotations have become stiff for this reason, as they usually follow steel and pig prices. Supplies of all kinds appear to be ample to take care of the demand. The non-ferrous scrap metals are not quite so active, but an improvement has been noted in the last few weeks. Local prices follow:

Copper, light per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Pittsburgh

October 4, 1922

STEEL markets have had another of the sudden shifts that are so characteristic. For six months mills have been straining every nerve to produce the last ton possible, in order to meet, as far as possible, the urgent requests of customers for deliveries, and during almost the entire period prices were advancing. The average advance on all steel products, for forward deliveries, was about $9 a net ton, or almost one-half again as much as the advances in the great market movements of 1909 and 1912, while using early delivery prices for the comparison, the advance was considerably more than $9 a ton.

By the sudden reversal that has occurred, mill deliveries on old orders are growing more prompt, many mills are eagerly seeking business, prices for early deliveries are declining, and a feeling is growing that prices for forward deliveries are likely to decline before there is another general buying movement.

Possibly this reversal is due to the increased production of steel since the coal strike ended, but this seems hardly sufficient to explain the change fully. Production was at about 50 per cent. of capacity at the end of August and is now at between 65 and 70 per cent. While this is a great increase, the 50 per cent. rate had been only a temporary affair. The industry was running at between 70 and 75 per cent. in June, and July showed an average rate of nearly 70 per cent. Thus the real picture shows, not that there has been an increase in the past 30 days, but that there was a period of just a few weeks in which production dropped. The present rate is hardly equal to the July rate and is well below the June rate, hence it should not, itself, make a surplus of steel.

The explanation of the sudden easiness of position the steel market has acquired seems rather to be that during the coal strike buyers were anxious to get all the steel they could, fearing an interruption of deliveries by the coal shortage while now, with the coal strike ended, they content themselves with such steel as they actually need at present. Possibly they are drawing upon stocks of steel previously accumulated.

Sellers of steel are laying much emphasis upon car shortage, presumably to encourage buyers to take heavy deliveries. The car shortage is not serious, as to its present influence, but it is serious in its menace of worse conditions to come, for inclement weather, due in say a couple months, always slows down railroad operations more or less. The demands upon transportation now are a little beyond the transportation capacity and if the demand for movement continues unabated and the capacity goes down there is going to be serious trouble.

Many of the mills, perhaps the majority, have more or less car shortage. At some sheet mills product to the extent of two or three weeks of production has accumulated. At mills making other classes of material there are no accumulations or only small accumulations, equal perhaps to two or three or four days of production. The greatest difficulty of course, is with box cars, required for moving sheets, wire products and tin plate, but open top cars are more or less scarce.

The sagging tendency in prices has been exhibited only by way of delivery premiums decreasing. Basis prices, for late delivery, are in no case a particle easier. In wire products there is an advance. The American Steel & Wire Company has made an advance of $2 a ton, to 2.45c on plain wire and $2.70 on nails. Independents had been $3 above the leading interest, this representing in essence a delivery premium and they have dropped the extra dollar, so that all sellers are now on the same basis.

A somewhat similar thing has occurred in merchant steel bars. The Carnegie Steel Company recently withdrew entirely its price of $1.90, leaving it on the basis of $2.00. One large independent, which had been asking and securing $2.15 to $2.25, according to size and character of order, has come down to $2.00. One or two others are already down and other mills are merely delaying, as they have some higher priced tonnage to complete. In shapes the regular market is now $2.00, with small and undesirable orders going at $2.15 or $2.25. Plates are at $2.00 to $2.25.

The price situation in sheets is rather complicated. The American Sheet & Tin Plate Company's prices are based on $3.35 for common black, but about three weeks ago the company became sold out, so that it has no more to offer until it opens books for the first quarter of the new year. Thus $3.35 is not really an open market price at all, though some shipping orders are being placed, filling out contracts not previously specified in full. Until the past few days the independents making the largest sales were getting a $3.50 basis, and able to make shipments on new orders in from four to six weeks. Others, able to make shipment in two or three weeks, were getting a $3.75 basis, the orders of course being small. In the past few days all or most of the $3.75 mills have come down to $3.60, making it possible that henceforth the $3.50 mills will have difficulty in selling much at their price. There is a possibility, therefore, that the whole market will gradually slide back to the $3.55 price.

The very unfavorable condition that has existed in pig iron for several weeks is being relieved slightly by offerings of the Cambria Steel Company, which is now operating six blast furnaces at Johnstown and has some pig iron over and above its requirements for steel making. Cambria has sold 2,000 tons of basic iron to the Follansbee Bros. Company at $30, Johnstown, and 1,000 tons of Bessemer to a steel foundry in the Pittsburgh district, at $33.50, Johnstown. Freight to Pittsburgh is $1.77, the same as from the valleys.

The pig iron situation lately existing proved an unfortunate one. Prices asked were in the neighborhood of $35 at furnace, and experience has shown that consumers are unable to pay such a price. Even if they had been able, they could not have secured much, as little buying would simply have sent the price higher still. Offerings of Connellsville coke are extremely limited and there is little chance for additional merchant furnaces to get into blast, so that relief from the steel works, which have coke ovens of their own, is for the good of the industry as a whole, though the few merchant furnaces that are trying to operate do not like to see the steel works entering their market.

Connellsville coke is somewhat higher, being now quotable at $12 to $12.50 for furnace and $13.50 to $14.50 for foundry. There has been quite a demand from retail dealers, for household use. Until a day or two ago, odd lots could be had at $11.50. Blast furnace lots have being going right along at $12 or $12.50, with little to be had even at that.

BOOKLET

The Alemite Products Co., Belleville, Canadian subsidiary of the Bassick Mfg., Co., Chicago, manufacturers of high pressure lubricating systems, have issued a booklet on industrial lubricating facts describing the application of their equipment. The Alemite method consists in the delivery of lubricant from a compressor through a flexible conduit to a bearing through a ball-check valve fitting, which remains a permanent fixture in the part where lubrication is needed. The system, it is claimed, is a time saver in the lubrication of intricate machinery, and practically eliminates the danger factor among operatives who have this work to do.

Canada's Foreign Trade is Making a Better Showing

In the four months to July 31st, the aggregate value of Canadian imports and exports, $479,500,000, was ten millions greater than in the corresponding period of last year. And the gain was in exports. We sold abroad $27,300,000 more of domestic products, and bought $17 600,000 less of foreign goods. The balance of trade in the last four months was $7,000,000 in favor of Canada, whereas a year ago there was an adverse balance of $38,000,000.

In examining the microstructure of a sand casting, it is seen that the structure is coarse and open grained in character, and that the lines of division of the crystals are pronounced. In examining the microstructure of the forging, it is seen that the structure is fine grained, compact and uniform, and that the lines of division of crystals are absent.

SELECTED MARKET QUOTATIONS

Few-Minute Interviews on Business Outlook

Managers and Purchasing Agents Express View That Conditions Steadily Improve—Import Steel Tonnages Double Those of Last Year—Car Shortage Increases Costs—Machinery Demand Better

F. C. BRUNKE, United States Steel Products Co., Toronto.—"Demand for steel covering a large variety of requirements in Canadian industry still maintains a good volume. There has been no falling off in structural steel as some might expect at this time, but you must remember that September and October are two big shipping months. The year to date has made a good showing, practically double last year's record. We hope for steady improvement in deliveries. The steel industry has passed through a strenuous time during the strike period and products have piled up in Pittsburgh and other district awaiting an opportunity to ship."

E. W. Knight, Frankel Bros., Toronto.—"Conditions throughout the country so far as we come in general contact, are good. There has been quite a sound development, with no evidence of anything making for depression."

W. M. Davis, Baines and Davis, Toronto.—"While the year, so far, has not been the best in the iron and steel business, development has been steady with no indication of unhealthy conditions. It is such a growth that counts, eventually, for business under those circumstances can suffer no delusions and more easily adjusts itself to requirements."

J. F. MacKay, general manager, John Morrow Co., Ingersoll—"Conditions in Ingersoll reflect general tendencies; while there has been no marked improvement, there is a feeling that we are moving in that direction. The prospect of war is a serious matter. It looks to me as though Turkey is disposed to go the limit in taking advantage of any break, however slight, among the allies. Money is likely to tighten, and industrial development along normal peace lines delayed, but we hope the trouble finds some solution other than war."

C. R. Peckover, Peckover's Limited, Toronto.—"In spite of encouraging crop reports, there seems to be quite a conservative tendency in the iron and steel market. There is a feeling that something is holding back, but it may be characteristic of unsettled conditions through which we are passing. Indications point to steady accumulation of stocks. Toronto prices, considering those of Pittsburgh and Chicago, have maintained very reasonable levels—in fact some opinions declare that they are too reasonable to absorb diminishing spreads."

J. Kingsnorth, of Jas. P. Scott and Co., Toronto.—"While non-ferrous metal markets are quiet, brass foundries throughout the country are all busy though there is an absence of what we might call any large undertaking. Where the metal market comes into contact with building industries, business shows greater activity."

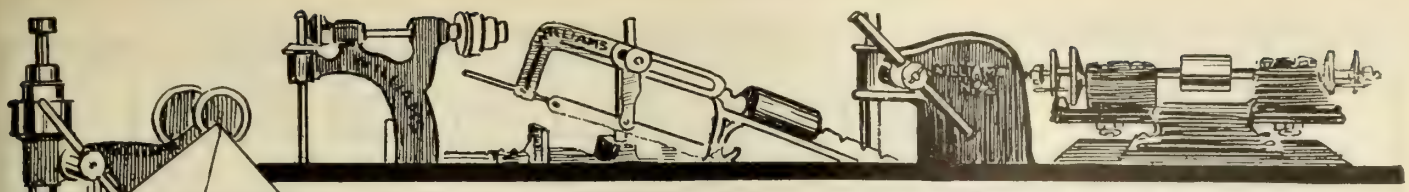
B. H. Neill, sales manager Canada Machinery Corporation, Galt.—"Industries in Galt are fairly well employed. The fact that railways have been coming into the market for machinery is a good sign. Should industry continue to improve, it would not surprise me to see still better business in woodworking machinery. Already we can see a preference developing for the latest types as being the more economical in the long run, for while manufacturing activities in general may have been below normal, there has been progress in machinery design. As to the price situation, I understand there is an upward trend evident on the United States market. Of course, owing to strong competition and the fact that raw materials over there went to low price levels, quotations on machinery had sharper reductions than elsewhere. Now that the term has come, and materials are up, prices on equipment are following and will probably continue firm for some months."

F. W. Evans, manager Canadian Fairbanks Morse, Toronto.—"Machine tools and supplies are showing improvement, although the demand is spasmodic. Our recent trip to the mines and pulp and paper industries of the north was a revelation. This market, by the way, is becoming increasingly important. All of the works visited had machine shops equipped with a view to their various requirements. Equipment and supplies of all kinds going into the north represent a very large yearly outlay. While the country's general aspect is not as flourishing as all would like, it is considerably better than has been. Although the crop is not yet marketed, there is no doubt about the demand being adequate. On many lines, the purchasing farmer will find prices that are quite as good if not better than in pre-war times. The manufacturers have learned the relation of production to low costs, and the farmer will undoubtedly reap some benefit from this."

C. S. Webber, purchasing agent, Page Hersey Tubes Limited, Toronto.—"A visit to the Pittsburgh district at the present time reveals the result of the coal and rail strikes as being more serious than we can ever imagine. My observations, among several of the more important plants, are that there seemed to be intense activity, and that immense tonnages of steel are being placed in storage owing to the car shortage. This means money and must add considerably to cost of doing business. All kinds of cars are being pressed into service; I saw some that seemed about ready to fall to pieces, but I would suppose these are used for short hauls. Prices are very firm, and the general attitude would indicate that they will be maintained for some time, although premiums for early delivery are disappearing. In my opinion there will not not be such revision of prices before the first quarter, 1923. Recent advances in pipe prices were long overdue, and the only change in sight, at the present time, is that in wrought pipe a flat discount rate, rather than a chain of discounts may be adopted. But this will apply chiefly to the Western territory. There is great activity in the steel industry in the States, with railroads doing much purchasing for track and rolling stock requirements."

Montreal:—Dominion Bridge Co. and Phoenix Bridge Co. have both tendered for the steel work of the new city hall. The lower of the two tenders was that of the Dominion Bridge Co. whose bid was $124,450. The figure asked by the Phoenix Bridge Co. was $126,655. The Dominion Bridge agreed to furnish to the city additional steel, if required, for the sum of 5 5-10 cents per pound, while the Phoenix Bridge Co. quoted 5 6-10 cents per pound. A condition of the specifications was that the work must be completed three months after the placing of the contract. Thus, if quick action is taken, the work can be completed this year.

Recent inquiries for Canadian products are reported as follows by Commercial Intelligence Branch, Department of Trade and Commerce:—No. 420—New York firm doing extensive business with Australasia and South Africa as specialists in machinery of all kinds, autos, electrical appliances and paper, would establish contact with Canadian exporters, with a view to organizing distribution. No. 418.—London firm desires to obtain agencies of Canadian makers of household utensils and domestic hardware specialties. No. 427:—Large South African firm wants to get in touch with Canadian manufacturers of galvanized piping, sheets, rails, hoops.



Machinery at Bargain Prices

The Williams' Monthly Machinery List is full of bargains in new and re-manufactured machinery—bargains worth your investigation. Each machine, whether new or re-manufactured, is backed by the Williams' Guarantee which means that no transaction is considered as concluded until the machine has proven satisfactory.

It will pay you to have your name on our mailing list.

News From the Industrial Field

Castrian Steamship Co., Quebec, capital $200,000 has been incorporated to engage in shipping and shipbuilding.

The International Harvester Co. recently re-opened their foundry at Hamilton, after a shut down of some months.

The general contract for the construction of a dock at Ford City, Ont., has been received by Merlo, Merlo and Ray. The cost will be about $100,000.

The Dominion Bridge Co., has been awarded the contract for fabrication of steel, roofing and skylights for a large apartment house on Bloor St., W., Toronto.

The contract for roofing and galvanized iron for the new $110,000 school board office building in Ottawa, has been awarded to W. D. Edge Co., of Ottawa.

McIntyre Bros., of Peterboro, Ont., have received the general contract for additions to the boiler room, pump house and coal bunkers for the Brinton Carpet Co. of Peterboro.

The Trussed Concrete Steel Co., of Montreal, has received a contract to supply the reinforced steel for the $200,000 school and residence for the Catholic School Commission of Montreal.

Steel Work for the new furnace building of the Abrasive Co., of Canada, to be erected on Burlington St., Hamilton, has been awarded to the Hamilton Bridge Works of Hamilton.

Signet Mfg. Co, Montreal, capital $550,000, has been incorporated to manufacture and deal in phonographs and machinery and apparatus used in their manufacture.

Lamoreux-Kelly, Limited, Montreal, capital $50,000, has been incorporated to manufacture and deal in railway, mining and general contractors' supplies and equipment.

Increased Activities are reported from the Canadian Firestone Fire and Rubber Co., of Hamilton. This plant has been gradually increasing its output and within a short time it is expected that a full staff of 500 men will be engaged.

Members of the Lake Shippers' Association are accused of discriminating against Canadian in favor of United States ports. Hon. J. A. Robb, minister of Trade and Commerce, has asked for an explanation.

George Barrett has been appointed to the position of general mechanical superintendent of Penmans Limited, Paris, Ont. Mr. Barrett has had a wide experience in a varied field of mechanics in various parts of the world.

Increase in the price of steel rails from $40 to $43, effective Oct. 1, brought out a large amount of business from the railroads. American roads came in to the extent of a million tons, and are buying material for much other equipment.

Engineering Alumni, Toronto University, will hold their fourth annual meeting and school reunion, Friday and Saturday, Oct. 27-28. The program will consist of class luncheons and dinner dance on Friday, and the annual meeting, buffet luncheon, faculty reception and football match, Queen's vs. Varsity, on Saturday.

Canadian makers of medium-sized cars will be interested in the fact that gasoline prices in Great Britain have been reduced to two shillings a gallon. In August, 1920, the price reached 94 cents. Owing to upkeep costs there have been practically no middle size cars in operation.

Toronto bankers, brokers and other business men recently visited the mining and pulp regions of northern Ontario, following upon the trip taken by Board of Trade representatives. This part of the country, of which comparatively little has been known generally, is receiving considerable attention from business and industrial interests.

Installation of chain drives by the Morse Chain Company in the Northern Central elevator at Baltimore totalled 7,000 horse power, and was not a single unit of 7,000 horsepower as a news item in these columns one week ago erroneously stated. This is one of the largest installations of chain drives in any elevator in the world.

D. A. Cameron, president of Toronto Board of Trade, addressing the Young Men's Club, stated that the curse of civilization was the inclination to look down on manual labor which if persisted in meant the downfall of the British Empire. He advised members as to the methods they should employ in private and business life, looking to greatest usefulness as citizens.

Building activities in Kitchener, Ont., to date show an increase of more than 100 per cent. over last year. The amount is $1,903,099. Galt, with a nine months' total, is slightly below last year, while Stratford reports a valuation of $660,346 on new buildings, the largest amount for fourteen years. Galt, however, reports as an indication of business improvement an increase of $37,632.23 in customs and excise revenue during the month.

Canada's fire loss in the past ten years has amounted to $250,000,000. This and the loss of over three thousand lives in that time, is the reason for the proclamation designating Oct. 2 to 9 as Fire Prevention Week. All schools, factories and theatres have been circularized with pamphlets, enumerating important facts, common causes of fires and precautions that should be taken to prevent them.

Canadian Locomotive Works, Kingston have started operations on contracts for the renewal of locomotives, manufacturing parts and making repairs. When interviewed, William Casey, general manager, stated that the work at present called for about ten per cent. of the staff, and he was not in a position to say just what would develop in the immediate future. About 75 men will be employed now. The works have been closed 14 months.

P. M. Laing, Toronto representative Jones and Glassco, engineers, has built for himself in spare time during the past year a 33-ft. schooner rigged yacht of the cruiser type. The hull is of yellow spruce, Douglas fir and oak and the craft has a sail spread of 605 feet. She is of a class that is popular with the Boston yachtsman and, up to the present time, not frequently seen in Toronto waters. Mr. Laing has made a hobby of yachts and yachting.

INDUSTRY ON UPGRADE BUSINESS MEN DECLARE

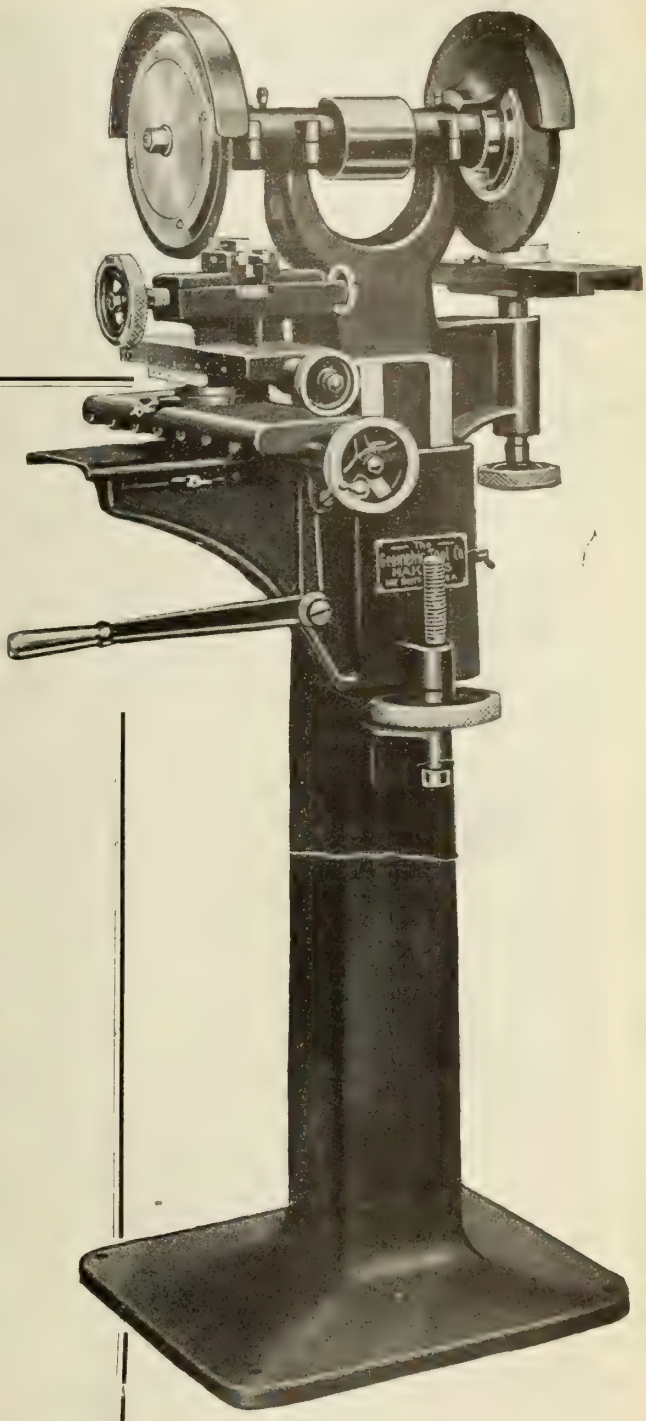
There is no question but that conditions generally are on the upgrade. During the past week Canadian Machinery has had short, informal chats with various keymen in different lines of business, and in every case reports have been encouraging.

For example, a manufacturer of motors states that they have had more enquiries lately than for some time past. A large percentage of these are developing into good-sized orders, and others looks very promising. He feels sure that those who have confidence to go after the business opening up will get it.

Mr. Newman, of the Canada Metal Co., is satisfied that things are on the mend. In fact, the improvement has been so steady and noteworthy that, in a recent editorial article, he commented as follows:—

> "We believe that there are few men today but who are interested in, and giving good thought to, the signs of the times and to business conditions and prospects generally as they appear to them, and, therefore, as

(Continued on page 56)



Sharp Chasers Cut Clean Threads

Accurate, uniform threads result only from dies which are maintained in the highest state of cutting efficiency. This means that chasers must be kept sharp, and ground uniformly.

Even if just touched up from time to time, the chasers respond splendidly, with clean threads. And with this machine—the Geometric Chaser Grinder—the matter of keeping threading tools up to scratch is a comparatively simple matter.

Various makes of chaser can be ground on this adaptable machine. The two wheels permit the easy grinding of both milled and tapped chasers. In addition, the plain wheel lends itself readily to various kinds of tool grinding.

Uniform grinding of a set of chasers is purely a mechanical matter through the use of adjustments which can be accurately set to govern the grinding of an entire set of chasers.

The Catalog describing this machine is a mine of information on chaser Grinding. Write for it.

INDUSTRY ON THE UP GRADE

(Continued from page 54)

we believe conditions as we experience them in our organization are a fairly good barometer, we want to express our views to you in a few plain words.

"There is not a shadow of doubt that there is taking place all around a steady, gradual, almost imperceptible improvement and a settling down to regular consistent business activities. The pessimism that existed with many for a long time is nearly forgotten, and today everyone is looking at the present and future with every confident feeling of optimism. The talk about 'hard times' and things being 'so bad' is heard less often, if at all, and men are realizing that it's 'up to one's self' and that times and conditions are very much what one is prepared to make them. We only get out of life, or any of its interests, just exactly an equivalent to what we put into it.

"The man who is still content to sit with folded hands 'waiting for good times' is going to be left behind, but there never was a time when opportunities were better for the man who is alive and prepared to buck right in, in an aggressive and intelligent way.

"Without question, labor is steadying down, and workmen are forgetting the big money craze that seized everyone when labor and products were scarce, and today many realize that money isn't everything, and that a good, steady job under ordinary and reasonable conditions brings equally as much and perhaps more satisfaction and happiness.

"There is one lesson that we in Canada can well take to heart from some of the happenings of the past few years, viz., our dependence on outside markets for a good many of our supplies, which, with a little enterprise and patriotism on the part of many of our capitalists, manufacturers, etc., could bear quite a different aspect. We can and are well able not only to look after our own requirements but to also take our place among the exporting nations. Let us wake up in this respect and only be satisfied when we see the sign 'Made in Canada' on all the world's markets. When we begin to build up production so that we can not only take care of domestic needs but also sell to outside markets, we are indeed helping our country to take a place in the world of commerce.

"However, we are emerging from a very critical time in a more than satisfactory way and we would like every one of our readers to feel as we do—confident and assured that we have seen the worst time through and that the steady return to prosperity going on all around us is in accord with the natural cycle and working back to the law of supply and demand, which for a time was forgotten, and this improvement will be helped forward just in comparison to the way in which each one of us is prepared to put his or her best efforts into 'making Canada.'"

Mr. Mitchell, of the P. B. Yates Co., Hamilton, says that enquiries for woodworking tools of all kinds are picking up. Quite a number of shipments have been made during September and a few more men have been added to the payroll. The orders received are not centred on any one type of machine but are general in character.

Mr. Davies, secretary-treasurer of the N. Slater Co., Hamilton, says they are very busy at present and finding conditions much improved. Their galvanizing departments are working night and day, and their electrical sections are also quite rushed. They find enquiries of much better volume and look forward to still further improvement.

Truman Norton, manager of the Wallace Barnes Co., Hamilton, spring manufacturers, states that they are getting good enquiries and orders, and that business generally is picking up steadily and surely.

Mr. Norton's remarks are typical of many others who have spoken with Canadian Machinery during the past week. The steady, healthy growth is the chief feature in business improvement. All seem agreed in the statement, "We would rather see it slow but sure than sensational, because the former will last, while the sensational improvement generally leads to future disappointment."

Tensile strength is the one most frequently considered. This is its ability to resist being pulled asunder.

Two Important Factors in Educational Work

Business and Technical Press and Canadian National Exhibition on Common Ground—Covering Every Line of Industry—Reaching More Than Three Million Students of Industrial and Commercial Affairs

POINTS of similarity between the work of the Canadian National Exhibition and that of the Canadian National Newspapers and Periodicals Association were emphasized by Horace T. Hunter, vice-president of the latter, on the occasion of an Exhibition directors' luncheon at which the gathering was representative of the daily and weekly as well as of the business and technical press.

Importance of educational work was the common ground recognized by both Associations, the speaker declared. The great success of the Exhibition was due to the fact that the amusement side had not been allowed to dominate, and such proposed work as the new Engineering Building and the several fine structures that had recently been completed in order to facilitate representative display of national products were significant of a vision keenly appreciative of educational objective.

"The extent and influence of publications represented by our Association," said Mr. Hunter, "are indicated by the following approximate statement of circulation:—

Farm Papers	1,030,897
Magazines	1,065,307
Religious and Educational Papers	725,000
Business and Technical Newspapers	399,099
Total	3,220,303

"We know that this Exhibition is not like Topsy, 'just growed.' It has been brought to the high state of perfection it occupies to-day by the shrewd and far-seeing policies of the directors and executive officers, and by their untiring energy in carrying out these policies.

Similar Aims and Interests

"There are many points of similarity between the work of our Association and the Canadian National Exhibition. These form a strong bond of interest and sympathy between us.

"Both are national. Our subscribers in the various provinces of the Dominion are the men and women you are most anxious to bring to the Exhibition. The fact that they are readers and subscribers of our papers is the proof that they are people of intelligence, students, interested in new methods and in learning of new goods. They are the people who will travel a hundred or a thousand miles when the opportunity offers to see an exhibition such as you have developed, and I congratulate you that these people are coming in increasing numbers each year.

"The international aspect is also a common bond. You have an increasing number of visitors from foreign countries, thus creating a feeling of goodwill with these countries, and helping our manufacturers to establish connections abroad. The same reason that brings business men from United States, Great Britain, West Indies, etc., also causes them to subscribe for our publications. These foreign subscriptions have become such a big factor with some of our publications that they are now issuing Export editions.

Educational Aspect Most Important

"Then we are on common ground in educational work. I believe this Exhibition was started primarily for educational purposes and its great success is due to the fact that you have never allowed the amusement side to dominate. I believe the educational features should be given wider publicity. The individual exhibitors do a good deal in this connection but there is much to be done collectively. A few people would come to see a few exhibits of motor cars, but thousands will come when they know there will be seventy exhibitors representing probably seventy per cent. of the manufacturers who are seeking Canadian business. In our Association there is a publication for practically every line of business. These publications have told, year by year, the outstanding events of the Exhibition that would be of interest to their readers, and I think we can claim that this has been a factor in increasing interest and attendance of a very desirable class of people.

Influence of Business Press

"I would like to quote briefly from an address delivered within the past year by His Honor, the Lieutenant-Governor of Ontario, who officially opened the Exhibition this year. Addressing the Canadian National Newspapers and Periodicals Association, His Honor said:

I believe that the influence of the business press will be one of the most important factors in re-establishing business conditions in Canada on a safe and sane basis. I make a distinction between the business newspapers and the daily press because I believe that your papers—the business newspapers of Canada—exert a greater influence than the daily press because of the greater confidence your readers have in them. People read the daily newspapers to keep abreast of the general news of the day. They are interested in what is happening around them and they read to satisfy their desire for excitement or interest or entertainment. What they read in the daily newspapers to-day is forgotten to-morrow.

But this is not the case with the business newspaper. Business men need the service of these papers in the conduct of their every-day business life. I have noted that they usually have a business paper or two in their pocket when they go home Saturday night. I do not say that they read them on Sunday, that I do not know, but I do know that they study them carefully and a great number of your readers will come to their business on Monday morning with some clippings from your paper in their pockets. They will say to their associates: "This is the situation, and I can show it to you in this clipping." For that reason, gentlemen, I say that yours is the greater obligation, you are the leaders, because you are helping to build up the business fabric of the country.

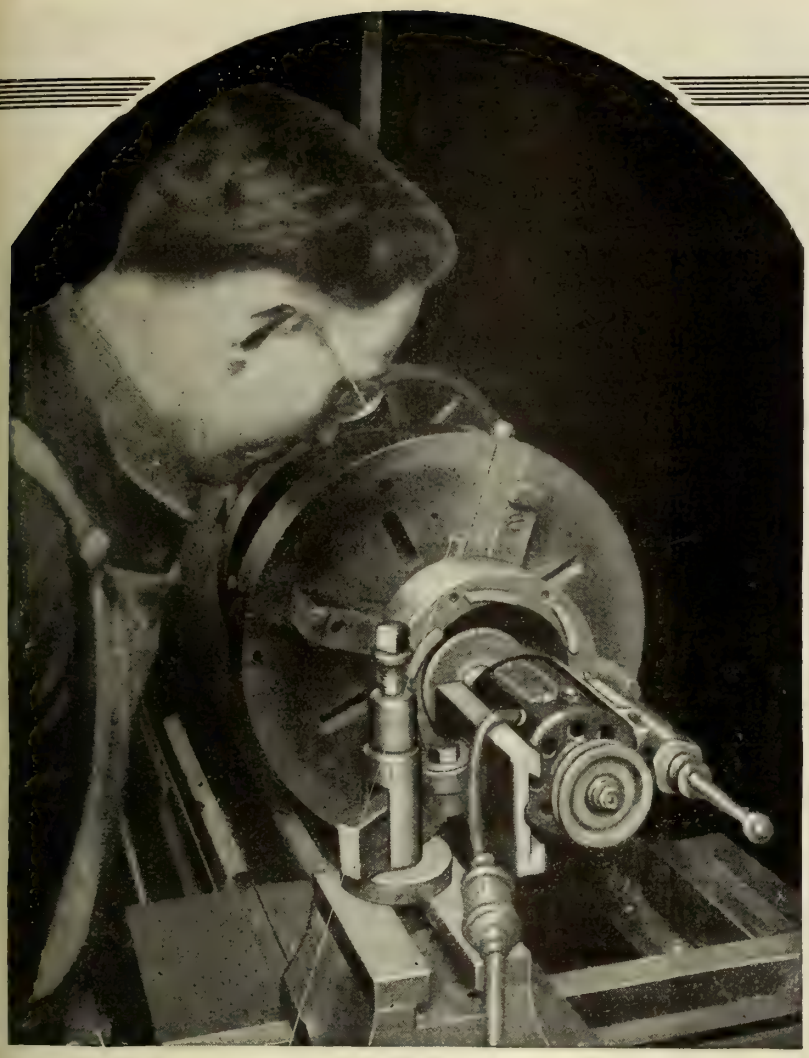
"We appreciate the honor the C. N. E. has conferred on the Press in singling out a day in their honor. In a larger sense, however, every day is 'Press Day' for some of the publishers in our association. Our publications are of such a varied nature and cover such diversified fields that in nearly every case there are one or more publications devoted to the industry that gives the day its name.

"Now, I believe the directors are interested not merely in bringing the numbers but in bringing the men and women with a stake in the country—the responsible people, the people of large buying power. To put it in newspaper language, you are interested in class in circulation rather than in the mass circulation.

"In every one of the lines mentioned above, our publications reach a large percentage of the best men and women engaged in the business, and reach them with publications that they have come to regard as their business associates.

"I believe the big development of the future for the Canadian National Exhibition is to develop the exhibits of the various industries as units.

"I can assure you the publications in our association will be very glad to cooperate with you, not only in organizing exhibitors and inducing them to guarantee the cost of the building, but in making the buildings a success after they are erected by bringing to the Exhibition the class of people these exhibitors want to reach. For, after all, the real success of an Exhibition does not consist in large buildings or elaborate exhibits but in the class of people who attend."



At the left is shown a DUMORE grinder attached to the toolpost of an engine lathe at the Geometric Tool Co., New Haven, Conn. A cam for a die lead has been just machined and the hole is being accurately ground without tearing down of the original "set up." Result—faster work at a decreased operating cost.

Thousands Now in Use

—*a tribute to* DUMORE *efficiency*

A FEW years ago the DUMORE line of high-speed grinders were new devices on the mechanical market. But to-day thousands of these better grinders have found their way into the tool rooms of the leading industries of the nation.

The many thousands of DUMORE grinders now in active service — their endorsement by the world's foremost mechanical experts — the numerous re-orders, *all* are tributes to the efficiency of DUMORE grinders more forceful than any other we know.

DUMORE grinders can meet *your* requirements for intricate grinding work as they have met the needs of over five thousand other industrial leaders. Set them up anywhere—use them for varied kinds of grinding. You'll find them equal to the task—performing swiftly, smoothly and accurately.

Be assured of correct cutting speed with a range of 10,000 to 30,000 R.P.M.—get accurate grinding to limits of .0001″—eliminate the costly need of tearing down original "set-ups." Put one or more of the DUMORE grinder family in your tool room!

Write to-day for complete information and descriptive literature—let your dealer demonstrate.

A Directory of Dealers will be Found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

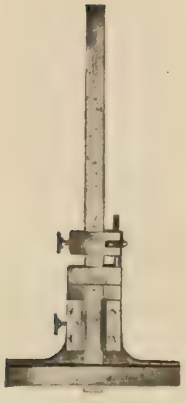
One Man Who Never Pounds the Pavement



Vernier Depth Gage No. 448

Invaluable where accurate measurements are necessary. For gaging the depths of holes and recesses in jig, die and fixture work, etc. Blade is 6 inches long and will measure to 3½ inch depth. Graduated by means of a Vernier to thousandths of an inch on one edge and to 64ths on the other.

The machinist who can do better than average work always has plenty to do. Good tools mean better workmanship—that's why you seldom see a man with a full kit of Starrett Tools burning shoe leather looking for work.

Write for Catalog No. 223 and the Supplement describing the new Starrett Tools.

False Economy in Files

You don't economize when you delay the replacing of a file that is getting dull.

Because a slightly worn file actually costs you money—in wasted labor-time.

These brands stay sharp until their full stint is done—you can rely on them.

The Bowser Oil Bank Will Give You a Check

To be absolutely sure that you get what you pay for in lubricating oil, check incoming shipments as barrels are emptied into the tank, then check the oil as it goes out by a meter on the Bowser piston-type measuring pump.

In this way, you are absolutely sure of getting full value for your oil dollars. Thus, the Bowser bank of oil tanks gives you a check on your oil.

More than that—the use of Bowser equipment insures you against waste. The pump measures the oil accurately, and if any happens to be spilled, it runs back into the pump through the Bowser drip pan.

For specific figures as to how you, too, can save money by installing Bowser equipment, write our engineers. Ask for booklet C-13, and get the whole Bowser story of economy and efficiency.

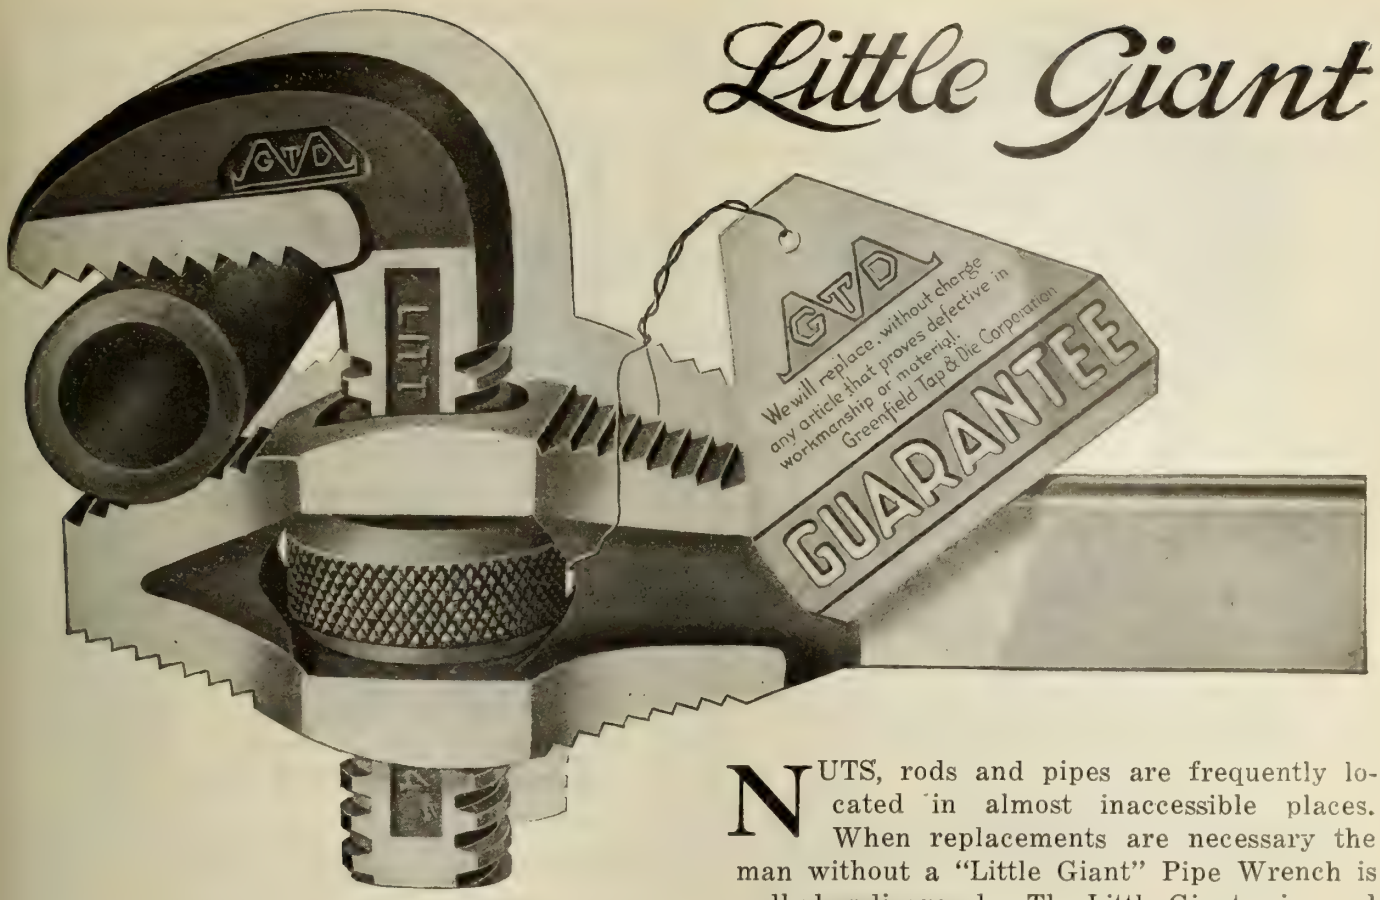
Little Giant



GTD
LITTLE GIANT
GTD
We will replace, without charge any article that proves defective in workmanship or material.
Greenfield Tap & Die Corporation
GUARANTEEE

Simpler— Stronger— Lasts Longer— only 3 parts

NUTS, rods and pipes are frequently located in almost inaccessible places. When replacements are necessary the man without a "Little Giant" Pipe Wrench is sadly handicapped. The Little Giant grips and lets go quickly and surely, and with it a much greater turn can be accomplished.

In running pipe lines close to walls, ceilings or corners the labor cost is apt to be high. It can be lowered by using the LITTLE GIANT WRENCH. The jaw opening can be thrust on to the pipe, rod or nut as easily as a pair of pliers. It grips instantly, gives a far greater turn and requires less muscular effort by reason of the extra long handle.

There are but three drop forged hardened steel parts in the LITTLE GIANT. It has two to four times the service life due to extra sets of teeth.

Hundreds of users have written us enthusiastic letters concerning LITTLE GIANT performance. You'll add to their number once you see it in action.

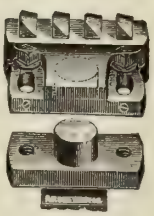
Saves 75% of Your Time On Large Surface Planing



The Armstrong Gang Planer Tool

is specially adapted for surfacing large castings. Its graduated head (which permits speed and ease in setting to any desired feed) makes possible the greatest speed on metals of varying degrees and hardness.

With this tool a planer will carry with ease a feed and depth of cut much greater than is possible with an ordinary tool and with less tendency to "break out" at the end of the cut.

Write for Catalogue.

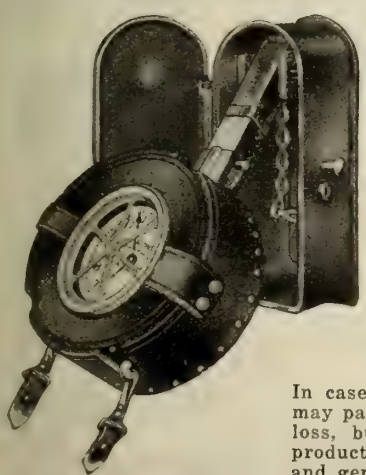
Why Take Chances?



The HARDINGE SYSTEM Protects You

In case of fire, full insurance may pay you for your property loss, but what about loss of production — the laid-off men and general disorganization?

The thing to do is to **prevent** loss and that is just what the Hardinge Watchman's Clock does. It keeps your watchman "on the job" whatever his inclination. With the Hardinge System installed you can rest easy knowing you are taking no chances. It's an **assurance against** fire or robbery and **insurance for** your steady income and production.

Where Simplicity Means Accuracy

TRADE MARK
BRISTOL'S
REG.U.S.PAT.OFFICE

Just as a straight line is the shortest distance between two points, so a Bristol Recording Thermometer is the shortest route from temperature to record.

Simplicity, it happens, is the keynote of the accuracy in Bristol thermometers. The two are complementary and Bristol users appreciate one as much as the other.

It is this simplicity that makes Bristol equipment so popular with firms that buy for service. You will appreciate it, whatever your thermometer applications may be.

Have you Catalog I-1202?

Producing Irregular Parts on the Turret Lathe

Experience of Others Often an Advantage—Economic Handling of Heavy Pieces—Fixtures Made to Accommodate Any Desired Shape—Special Boring Heads for Taper Work

IT IS seldom that two manufacturing plants are required to solve their machining problems in exactly the same way, as production methods must necessarily vary according to the nature of the product. Nevertheless, while the experience of any one particular manufacturer cannot be taken as an absolute criterion, the degree of success that has been achieved in one plant frequently creates considerable interest in those who have similar problems to contend with, so that any records of work performed help in deciding on the most suitable class of equipment to instal to meet the requirements of modern practice in the way of quantity and quality production.

Fig. 1 illustrates a line sketch of a clutch cone gear, and an interesting piece of work satisfactorily handled on a heavy-duty turret lathe. The entire surface of the part is machined to the dimensions shown, with the exception of the second interior cone section. The work is completed in two operations. Figs. 3 and 4 show the two operations respectively while Fig. 5 illustrates the style of taper boring head used for boring this particular type of gear. It will be noted in Fig. 3 that in the first operation the clutch cone gear is held with the large conical end next to the chuck in special hard jaws bored to fit the outside tapered surface. The order of operation is very simple as on the first operation the hub is faced, the hole is rough and finish bored and reamed to size. The heavy stock on the outside of gear is (1) roughed off with tool in tool post and immediately following the (2) facing head in turret is brought up which turns and faces the gear (these two operations are done almost simultaneously). The gear is then finished turned with tools in facing head.

In the second operation the piece is reversed and gripped on the outside of finish gear with soft jaws bored to size. The outside tapered surface of the cone is rough and finish turned by tools in tool post, then the inside tapered surface is bored with special boring head shown in Fig. 5. The inside and outside are bored simultaneously as can be noted in Fig. 4. Both the tool post tools and turret tools are shown in action.

Sectional drawing Fig. 5 illustrates the action of the taper boring head in connection with the cone. The cone is shown in slightly different design, but the principle is the same. The taper for the friction is bored with a single

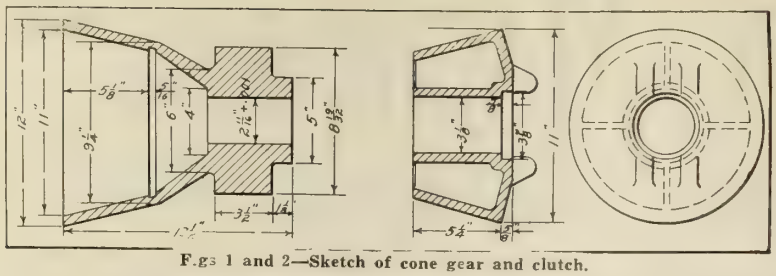

Figs 1 and 2—Sketch of cone gear and clutch.

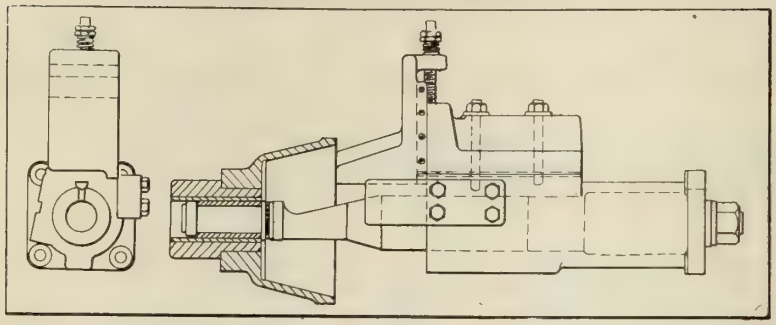

Fig. 5—Special boring head used in machining tapered cone.

point tool which is properly supported and guided to produce the correct angle. The operation is as follows: The pilot enters the bushing on which the clutch cone is centered, this insures that the friction will be concentric with the hub, a ball thrust bearing is provided at (A) and this bearing bears against the end of the bushing in the chuck, this keeps the pilot from entering further into the hole and the length and location of the taper is governed by it. As the boring head is feeding forward over the pilot, a pin resting against the angular surface (B) guides the tool in at the proper taper, the slide holding the tool being forced down by a spring as the head feeds forward.

The recess at (A) (Fig. 1) is cut with tool shown in frontside of tool post in (Fig. 4). This recess provides clearance for the tool in the taper boring head mounted in the turret (Fig. 5). The time on both these operations is 60 minutes complete.

Let us next consider the cone used on this gear just described. The piece is shown at Fig. 2 and fits into the clutch cone gear in Fig. 1. This piece is made of cast iron and is finished on the bore, counterbore, face, outside taper and small section on back face. Two settings are necessary to complete the part, and Fig. 6 and 7 illustrate both operations on this piece. In the first operation, the piece is held with special hard jaws gripping it on the inside of the small end of taper. The outside is then rough and finished turned with tools held in the tool post and at the same time the hole is roughed and finished bored and reamed with tools in the turret. The work is held by soft jaws in the second operation and is gripped on the outside of the large end of the tapered surface as shown in Fig. 7. The small end of the cone is then faced by a tool held in the tool post; this completes the operations. The total time required for both operations is 25 minutes.

Tractor Axle Arm

What at first would appear a very difficult turret lathe job is that illustrated in Fig. 8. The peculiar shape of course makes it necessary to employ special holding fixtures, but where sufficient pieces are produced the construction of such appliances is offset by the advantages in machining the parts by the multiple tool system of the turret machine.

Fig. 8 shows an irregular piece machined on a 24in. turret lathe. This arm is made of cast iron and is machined as indicated by heavy lines. There is no difficulty in finishing an irregular piece like this one provided it is held rigidly as indicated in Figs. 9 and 10. The first operation is shown in Fig. 9. The piece is first roughed and finished on the surfaces marked (A) and (B). This is done with tools held in the tool post. The time required is nine minutes.

The tool layout for the second operation is shown in Fig. 10. The work consists of boring the hole on outward end of the arm and facing the flange as well as facing the rear side of the hub at (E). The work is first placed in a special fixture which is clearly shown in Fig. 10. One: the piece is held by clamps that force the finished bottom flange against chuck plate. In addition to this, an auxiliary supporting clamp is used, thus steadying the arm near the end where it is machined. Two: flange C is then rough faced by means of tool (A) in tool post. Three: hole (D) is rough bored with cutters held in boring bar side one of the turret. Four: the hole (D) is then finished bored with cutters held in boring bar side 3 of turret. Five: hole (D) is reamed to size with a floating reamer held in side 5 of turret. Six: the face (C) is finished with tool (B) in tool post. Seven: the back of hub face (E) is then machined with tool in tool holder (C) in tool post. Total time for this operation is nine minutes.

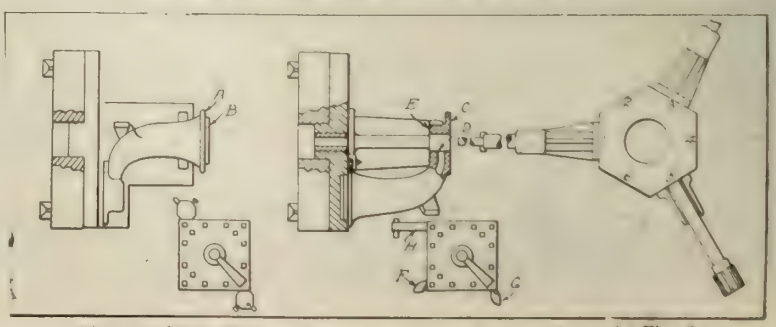

Fig. 9 and 10—First and second operation on piece shown in Fig. 8.

Some Notes on the Care of Pneumatic Equipment

Light Bodied Oil Best for High Speed Reciprocating Tools—Avoid Throwing Hammers on Sand Floors—Keep Service Lines Free of Dust—Daily Inspection Advisable

By F. A. McLEAN

LIKE all other machinery, the satisfactory operation of pneumatic tools depends to a large extent on the attention paid to their care. Pneumatic tools are high speed machines made with the same skill and attention to details that characterizes a fine watch, and in spite of the special kinds of steel and heat treatment used in their manufacture they are subject to wear in time. Especially is this true of such parts as pistons, valves, connecting rods, bearings, etc., where the wearing surfaces are necessarily limited in size and wear may be particularly destructive of economy through increasing the air consumption and shortening the useful life of the tool; but the rapidity of this wear is greatly reduced by keeping the tools clean and properly lubricated.

All manufacturers of pneumatic tools provide means for their proper lubrication. Instruction tags are usually attached to the tools when shipped, and should be kept for future reference when the tool is unpacked and put into service. Oiling and cleaning are too often delayed until the tool actually refuses to work. Tools of the reciprocating type, such as riveters, chippers, sand rammers, etc., require a high grade, light bodied oil such as the Vacuum Oil Company's Arctic Ammonia. This may be poured in at the hose connection of the tool every two or three hours when it is in continuous operation, as the air has a tendency to blow the oil out through the exhaust, or one of the small automatic oiling devices now on the market may be used, in which case the oil supply will only need replenishing once a day. Oil applied around the chisel shank in chipping and caulking hammers, will make them last longer, particularly if care is taken that all burrs or rough spots are removed from the shanks before they are put into the tool. These burrs quickly wear out the bushings which cost more than the amount saved in the cost of the chisels.

On drills of some makes such as the Thor and Little Giant, grease should be injected into the crank chamber and a light mineral oil used on pistons and valves, while in those of the Little David type this is not necessary as, due to the method of construction, the lubricant is fed from the crank chambers to the pistons, and as the crankshaft revolves all moving parts are flooded with lubricant. The best way of introducing grease into pneumatic drills, is to inject it into the dead handle by means of one of the small grease guns now on the market which have an opening in one side through which they are refilled. When drills are operated in a vertical position for any length of time, it is a good plan to invert them occasionally to ensure an even distribution of the grease to all of the working parts. Sand rammers and other tools used in dusty places obviously require more oil, and should be cleaned more often than those which are used under more favorable conditions. The moving parts of these tools are ground to very close limits, sometimes one-half thousandth of an inch or less, and may easily become clogged up with dirt if the proper precautions are not taken to guard against this. Some men unthinkingly throw their rammers or chippers on to the foundry floor at noon when the whistle blows, instead of laying them on a board or box to keep them out of the dirt.

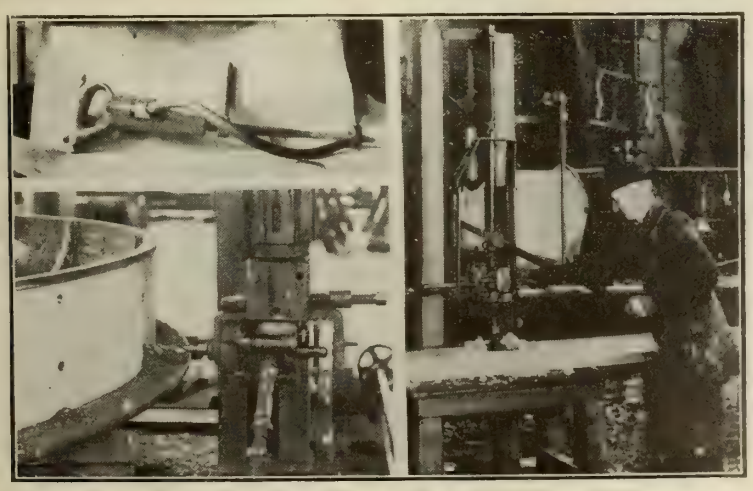
The air taken in by the compressor sometimes contains particles of dust which are blown into the tool, clogging up the parts and interfering with the proper action of the pistons and valves. For this reason a strainer should be placed over the intake of the compressor. Such a strainer is easily made by placing a box over the pipe and covering the open side of it with muslin. Heavy oils will cause the same trouble through gumming and are thus to be avoided. Where there are a small number of tools in use it is a good plan to clean them at intervals by pouring kerosene into the throttle handle that will cut the thick oil and loosen the dirt, which may then be blown out under air pressure. Moisture in the air causes the pipes to rust, and pieces of scale get into the tools unless the pipes are blown out before the tools are attached. No matter how good the hose is, it will rot in time and pieces of it are likely to get into the tools and cause the moving parts to stick. An easy way to prevent this trouble is to use a strainer in the supply line, which can be made by bolting a piece of wire netting between the two halves of a flanged pipe coupling, or a special strainer may be inserted between the tool and the hose nipples.

In Charge of One Man

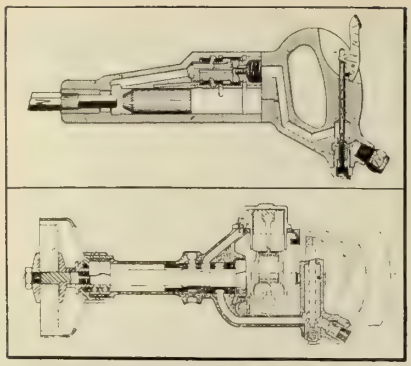
Where there are a large number of pnuematic tools in use, as in large ship yards, steel plants, etc., it is advisable to put them in charge of one man who will hang them in a tank of kerosene and gasoline in the toolroom each night in such a way that the dirt which falls out will go to the bottom of the tank. In the morning he should blow out each tool and re-lubricate it with light oil, as kerosene and gasoline while well adapted to loosening dirt, leave the wearing surfaces dry and bare. A galvanized iron box about two or three feet square and one foot deep fitted with a tight fitting cover, will make a suitable tank for this work and will hold a number of tools at one time. Immersing tools in this tank for ten minutes will often cure some of the minor troubles which sometimes occur, such as a sticking valve, etc.

Works Within Tool Capacity

It is not a good thing to apply pneumatic tools to work beyond the range of their capacity as specified by the maker, as it causes undue strain and wear and soon results in loss of power. One of the worst abuses to which a pneumatic hammer can be subjected is the substitution of pistons other than those supplied by the maker. An air hammer as it leaves the factory is properly designed and balanced for the work it has to do,



Top left—Home made drill for concrete. Lower left—Using pneumatic drill on vertical boring mill. Right—Home made drill press in wood-working shop.



Top—Sectional view of "Little David," chipping hammer. Lower—Pneumatic grinder.

as the result of a long series of costly experiments.

Avoid Short Pistons

Some would-be genius discovered that by cutting, say a four-inch standard piston down to two and one half or three inches, he could make the tool deliver a more powerful blow and for a short time increase its speed and output. Short pistons have too little metal in them to absorb the force of the blow, and the heat-treated surface is ground away. Heat treatment, as anyone can observe by examining a broken piece of treated steel, renders the metal hard, close grained and tough, to a certain depth, and grinding the piston down cuts this heat-treated surface away and exposes the soft porous centre, which soon becomes battered and chipped by the percussion of the piston on the chisel or rivet set. The broken particles cut and score the cylinder walls or become jammed and cause cracking, so that the tool is ruined in a short time.

Service Inspection

When a hammer does not appear to be standing up and the cylinders, handles and sets, or ends of chisels, are broken or chipped, the tool should be examined to see if the piston has been ground away. In some shipyards in the United States, it was at one time customary to carry out an inspection in army style while the tools were in operation as it was found that some of the men—usually unskilled labor, or foreigners—were carrying short pistons around in their pockets and substituting them for the regular pistons after having drawn their tools from the tool crib, and then putting in the proper piston before turning the tool in at quitting time. Generally where this practice is in vogue, the tools will appear battered as few of the men have the lead or copper hammers—which should be part of the kit of every pneumatic tool repair men—at hand, and are therefore forced to use other means of removing and replacing the handle. This practice also is the cause of stripped threads in the types of hammer in which the handle is screwed on to the barrel or cylinder.

While there was some excuse for shortening the pistons from the operator's point of view, due to the excessive vibration, heavy blow and slow speed of the long piston hammer of a few years ago, there is no need for it in the case of modern long stroke pneumatic hammers, in which pistons two and one half to three inches long are used, and such methods are unfair both to the firm who own the tools and to the man who made them.

Keep Tools in Order

All drills should be inspected daily to see that bolts are tight and that all moving parts of the tool are operating freely. Hammers should be inspected for loose handles, and kept properly tightened. Good operators always hold their hammers firmly against the work as they know that if the set or chisel is allowed to play in and out of the hammer it will soon result in damage to the tool. In starting to drive rivets in cold weather, especially in exposed places, it is advisable to warm the hammer slightly, as this will reduce the chances of the rivet set being broken by the blow of the piston. After a few rivets have been driven, the heat will keep the set warm enough to prevent the likelihood of this trouble occurring.

Chisel Breakage

A case of abnormal chisel breakage which came to the writer's notice not long ago, was traced to the blacksmith of a large industrial plant who was in the habit of stamping his employer's initials on the shanks of the chisels when they arrived from the factory. In order to do this he had to heat the shanks, and this destroyed the heat-treating and weakened the shanks, causing a lot of trouble and annoyance to all parties concerned before the reason was discovered.

Repairing Air Tools

When repairing pneumatic tools, care should be taken to keep the parts of one tool separate from the parts of another and not have the parts of half a dozen tools all intermingled on top of a dirty work bench. A bench covered with sheet zinc or galvanized iron, is well suited for the repair of pneumatic tools. If care is not taken to get the parts into the tool from which they came out, it sometimes happens that the alignment of the tool is poor and trouble will be experienced. Pneumatic tools are as highly interchangeable as it is possible to make them, but there are always some parts which are fitted for each tool, and another reason for using care in this respect is, that hardly any two tools will wear exactly alike, and after two tools have been in service some time, parts which are a good fit in one might not be so in the other. A piece of ⅜in. hose connected at one end to the air supply line and carrying at the lower end a nozzle of the blow gun type, is a handy addition to the repair man's outfit for blowing dirt from the tools and cleaning off the bench.

Where the number of tools in use justifies it, the repair man may keep one as a standard by which to compare the hammers that are brought in to him before putting them back into service. By operating this standard against a heavy block of wood and noting how far the die penetrates, how fast the tool runs and how much vibration is set up, he is better able to judge when the tool he is putting in shape is ready for service by trying it out in the same way and noting how it measures up to his standard. In large plants where there are a number of tools in use a card index should be kept on which are entered the symbol or number of each tool, the date of its purchase, names of the men who handle it, how many times it has been overhauled, etc. Sometimes the repair man will be told that a tool is not working right when it is really low air pressure or a plugged hose which is at fault. This is easily detected by comparing the hammer with the standard and it is then a simple matter to remedy the trouble.

Lathes, planers, milling machines and other machine tools are products of fine material and skilled workmanship, but when we compare them with the pneumatic tool it is evident that the latter is a much finer piece of mechanism. Intended for portable use it must be light enough to be conveniently handled, and at the same time must be capable of delivering great power at high speed and while other machine tool equipment is used in shops or tool rooms under favorable conditions, the air tool is exposed to all weather conditions, dust, dirt, and hard knocks of all kinds; and while some of these conditions are inevitable many of them may be avoided, and it is hoped that the foregoing suggestions may be of help to the user of air tools in obtaining the best kind of service from their use.

Some Useful Notes on Case Hardening Practice

Bringing About a Physical Change in the Surface Metal—Excess Carburising Should be Avoided—Careful Packing of the Treated Articles—Boxes Made to Suit the Parts

PREVIOUS to 1914 only a few of the most progressive firms in the engineering and automobile trade possessed any definite knowledge of heat treatment of metals. The result was that many firms were called upon in the early days of the war to do case-hardening who had neither the knowledge nor the equipment necessary to produce satisfactory work. The result was that a good deal of guesswork and many experiments had to be done before success was achieved.

The Ministry of Munitions, by collating what knowledge was available, brought the science of heat treatment very much to the fore. Other spheres of activities interested in heat treatment acquired much valuable information, and the following few plain facts may prove useful to the small manufacturer who has not the means at his disposal to call in the assistance of the chemist.

The case-hardening of an article is achieved by two distinct processes, says the Machine Tool Review. The first is that of changing to a required depth the chemical composition of the surface of the steel. The second process is to heat treat, to bring about a physical change in the part thus treated. Case-hardening with up-to-date equipment is now quite an easy process and readily mastered by anyone of average intelligence. The chief factors on which successful case-hardening depends are:

1.—The choice of the cement or carburising agent.

2.—The manner in which the articles are packed.

3.—The temperature reached by the article.

4.—The absence of fluctuation in temperature during carburising.

5.—The type of furnace used for the final heating process.

6.—The quality of the material used in the manufacture of the articles.

We will deal with each of these points separately.

1.—It is essential that the cement shall not carburise the articles fiercely, as is the case with compounds containing a percentage of the volatile cyanides. At the same time the requirements of modern machine shop practice demand that it shall be quicker in its action than the numerous compositions of charcoal and bone black now on the market. It must produce a carburised zone (the case) in which the carbon concentration gradually diminishes.

2.—The packing of articles in the boxes is a matter of great importance if uniform results are to be obtained; far too little attention is given to this point. As far as possible the boxes should be made to suit the article to be carburised, such as circular boxes or tubes for gear wheels and similar parts. Small pieces, such as gudgeon pins and bushes, should have tall narrow boxes, taking one row only in width and as many layers in height as the furnace will conveniently take without being too near the arch.

The luting of a box is an operation often very carelessly carried out. The best of fireclay will always crack sufficiently to allow any excess of gas generated in heating-up to escape. Therefore the more hermetically a box is luted the better. The clay should be worked until it has a silky and uniform feeling, its consistency being such that a small saucer is easily modelled with it. The boxes should not be luted until the whole furnace load is ready. When a box is ready to go in the furnace it is advisable to run a wet brush round the surface of the luting; this tends to make the shrinking of the clay uniform and the cracking fine and hairlike.

With large boxes hearth contact should be avoided. They should in some way be supported off the furnace floor, either on pipes or angle iron. This enables the hot gases to circulate entirely around the boxes.

3.—On ordinary work a temperature of 900 deg. C. is the most suitable, but with boxes of large dimensions 920 to 930 deg. C. is necessary. With circular boxes containing small gears of fine pitch and requiring an egg shell case a temperature of 920 deg. C. is best, in order to get higher carbon concentration in the case. It is impossible to get good results without a pyrometer outfit of reputed make. The thermal couple outfit is best for this class of work.

4.—Fluctuation of temperature is responsible more than any other cause for cracking or exfoliation of the cemented pieces. This is especially noticeable with coal-fired furnaces.

5.—The type of stove most suitable for the heat treatment of the cemented work is the natural draught or low pressure gas and air furnaces. It is advisable to set the burners to get a little higher than the required temperature, say, 20 deg. C. above, with the damper well open, and then gradually close the damper to effect the required reduction of temperature. The atmosphere in the furnace will then not be oxidising nor too reducing, and the work will heat up more uniformly.

The most suitable position for the thermal couple is on the centre line at the back of the furnace not more than six inches above the floor. After carburising, the boxes should be cooled as quickly as possible by standing them on two blocks of rollers and **not** stacking them close together. The work, when cold enough to handle, is brushed clean and loaded into the re-heating furnace in a suitable manner; some work may be placed in perforated trays or on wire, or any suitable rig to take a quantity. The furnace should be kept at or near 900 deg. C.; on charging, the temperature will drop; as soon as the work is red hot a steady recovery will be noted. When the temperature again reaches 900 deg. C., carefully watch the work and note when the color of the work and couple stem are alike. When this occurs the parts should be left to soak for three or four minutes, according to the size of the article, to ensure an even temperature right through. Then they are quenched in oil or water (oil for preference), and may be withdrawn from the quenching medium as soon as black; this will lessen any strains existing.

This is called "regenerating quenching," and its object is to restore the core or soft part of the material, coarsened through the long exposure at a high temperature in the carburising process, to its original structure. It also produces a more or less complete solution of the lamina of cementite, the permanence of which in the cemented or hardened zone is known to constitute one of the most important causes of brittleness.

A second quenching is now necessary to complete our object. This may be termed the "hardening quenching," and may also be considered a regenerating quenching for the steel of the carburised zone. The temperature at which this is carried out is from 760—800 deg. C., according to the weight and mass of the pieces.

It is not necessary to soak the articles any longer than sufficient to ensure that this temperature is thoroughly uniform throughout the whole of the cement zone. They may then be quenched in water and kept in until cold enough to handle. Small gears and very thin articles may be quenched in oil.

6.—Too much importance cannot be attached to the quality of the steel used for case-hardened articles. The carbon content must not exceed 0.2 per cent. A good specification for ordinary rolled case-hardening steel is:—Manganese, not over .5 to .6 per cent. Sulphur, not over 0.05 per cent. Phosphorus, not over 0.05 per cent. Carbon, from 0.16 per cent.

Machining Cylinder and Ball and Socket Bearing

Advantage of Permanently Set Tools—More Time Available for Actual Machining Operations—Unnecessary Gauging Eliminated —Increasing Output With Same Overhead

WHEN a number of tool changes are required in the machining of any particular piece of work, and the production is of sufficient volume to warrant the installation of special equipment, the problem of manufacture is largely limited to the conservation of time in setting up and handling the work. The actual cutting of the metal may be the same no matter what method is adopted but the labor involved and the elapsed time between the start and finish of the total operations may be such as to prohibit manufacture, or to do it at a relatively small profit.

The purpose of modern engineering is to utilize every available moment of time in actual production and all unnecessary time and labor eliminated or reduced to the lowest possible factor. Where interchangeability comes into the problem the constant changing of tools is almost prohibitive. The time required in resetting tools and the subsequent gauging would make standardization a very difficult proposition, where large production is required.

The heavy duty turret machine is probably the one most adaptable to a wide range of manufacturing. Its construction offers an almost unlimited number of tools to be used which can be brought into consecutive operation with the least amount of physical effort and with a great degree of accuracy. Each tool is set and adjusted individually and when once located in the exact position for its own special service can be relied on to retain that position until it is required to be removed for regrinding, and where roughing and finishing tools are used, the working period of any tool is greater than when working under constantly changing conditions.

As an example of what can be performed on a heavy-duty manufacturing turret lathe, the views herewith are shown. Fig. 1 illustrates a dimensioned sketch of a cast iron cylinder machined on a turret machine. The work consists of boring to a diameter of 5.745in. counterboring to a dia. of 5-25/32in. and 1-5/16in. deep, facing and chamfering, and turning the outside rim to 6-15/16 in. dia. The time for the complete operation on the turret lathe was 15 min., whereas, the previous time in the engine lathe was just over an hour. This gives a saving in time of about 47 min. Figured on the basis of 60c an hour labor rate and overhead of 1½, the actual cash saving comes to about $1.18.

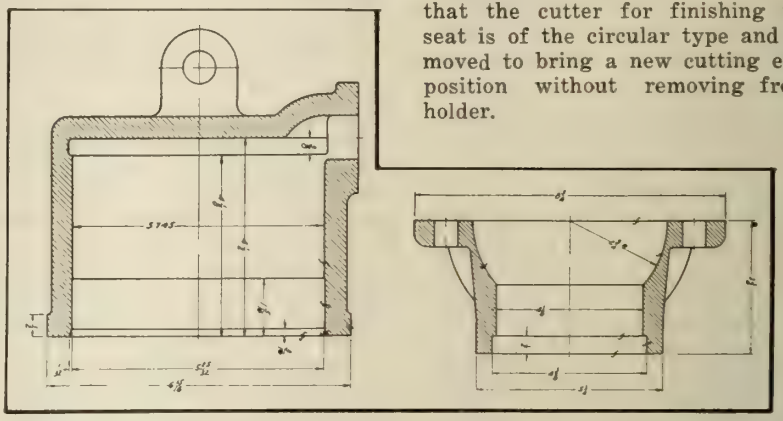

Fig. 1.—Left: cast iron cylinder, machined on turret lathe. Fig. 2.—Right: cast iron box ball and socket bearing.

A piece requiring additional tooling is shown in Fig. 2. This is a cast iron box ball and socket bearing. The machining details consist of boring to 4⅛in. dia., face of both ends to an overall length of 3¾in., recess at back to dia. of 4⅜in. and ½in. deep, turn ball socket to radius of 2¾in. This piece is completed, floor to floor, in 16 min., against the former method when 73 min. were required. At an operating cost of 60 cents an hour and 1½ overhead, the saving effected on this particular piece amounted altogether to more than $1.43.

Fig. 3 shows the machine set up to perform the operations on the piece illustrated in Fig. 2. It will be noted that the cutter for finishing the ball seat is of the circular type and may be moved to bring a new cutting edge into position without removing from the holder.

MOISTURE IN TURBINES

I recall that while I was a student in college I interrupted an instructor in the course of a lecture on steam turbines and asked him whether moisture in steam passing through steam turbines was as undesirable as moisture in steam for driving reciprocating engines. It is plain now that I was ahead of the times with my query. It was much like asking, at the present time, "Through what gas can a flying machine fly with greatest safety?" The professor was not to be stuck, however, for he immediately came back with the reply: "A steam turbine, Mr. Near, is not a water wheel."

We know now, from a structural standpoint, and even from the standpoint of ultimate efficiency, that moisture in steam when used for driving steam turbines is even more undesirable than in the reciprocating form of prime mover. Moisture striking the blades at the high velocity of steam is bound to cause wear and as soon as the outer crust is worn through the wear becomes quite rapid. Wear in the blading decreases efficiency. Where the water used in boiler is impure, and especially where it contains acid, the acid is liable to be carried over with the moisture particles and hasten the erosion. Sometimes solid deposits are found on the blading of turbines which have been carried over with the moisture.

With a proper reflector, illumination can usually be increased without any additional expense for current, but with a marked increase in the efficiency of the workmen, who are thereby freed from a wholly needless handicap.

Application of the Chain Drive to Machine Tools

Initial Cost Slightly Higher But Efficiency High—Slip Eliminated —Effective Operation on Short Centre Distance—Comparatively Silent in Action—Study of Various Designs

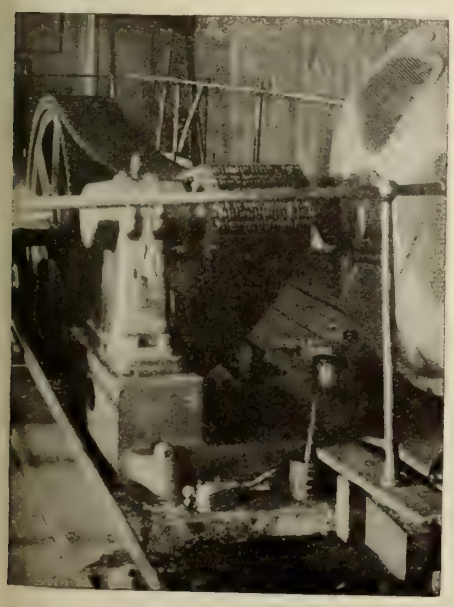
By HUBERT BENTLEY, A.M.I.M.E.

RAPID STRIDES have been made in the application of chain and sprocket wheel drives to machine tools during the past few years. In fact there are few branches of engineering in which the chain drive is not now employed. The early days of the chain drive, of course, centre around the cycle and automobile industries. When once satisfactory results had been attained in this branch of engineering, in which the conditions may be claimed to be the least favorable to the chain, fresh fields of application were sought and without doubt machine tools have proved a very fertile ground. The chain drive is today a factor to be seriously taken into account in every branch of engineering practice due to the many advantages it affords over other methods of power transmitting.

The three systems of transmitting power usually available in the modern machine shop are: (1) the belt drive, (2) the gear drive, (3) the chain drive. Both the belt drive and the gear drive in certain instances are, of course, more suitable than the chain drive, while on the other hand, the chain drive undoubtedly can show advantages over the two first named systems in many workshop applications. While the initial cost is generally higher than the belt or gear drive, the fact that the chain drive tends to improved conditions in the workshop and is, therefore, to the welfare of the worker, apart from its other advantages, should be sufficient reason for giving it serious consideration in these days.

Chain Drive Application

Undoubtedly the increased use made of electric motors for driving individual machine tools and also for the group systems of driving has been a large factor in the development of chain driving in the modern engineering works. Today the chain drive is frequently substituted for: (1) a rope or belt drive from the prime mover, engine or motor to the lineshaft, (2) for a belt drive from a line shaft to a countershaft, (3) for a belt drive from a countershaft to a machine, (4) for a gear drive in a self contained electrically driven machine tool, (5) and is now being more frequently adopted for the auxiliary drives such as feed motions, power transverses and suds pumps, etc.



Large Chain Drive Installation.

Just as in certain cases the belt or gear drive is undoubtedly correct practice, similarly with the adoption of a chain drive there is obviously hardly any necessity to consider the matter at all. On the other hand, there are many cases where the pros and cons of the different systems are carefully considered and where the various initial outlays are set against the various advantages and disadvantages accruing. As every up-to-date engineer and machine tool designer is keen to eliminate all sources of waste it is only natural that the method of transmitting power should receive careful attention. Every foot-pound of energy wasted between the prime mover and the machine is a foot-pound less available for useful work. A study of the advantages claimed for the chain drive over the belt and gear drives will now be made.

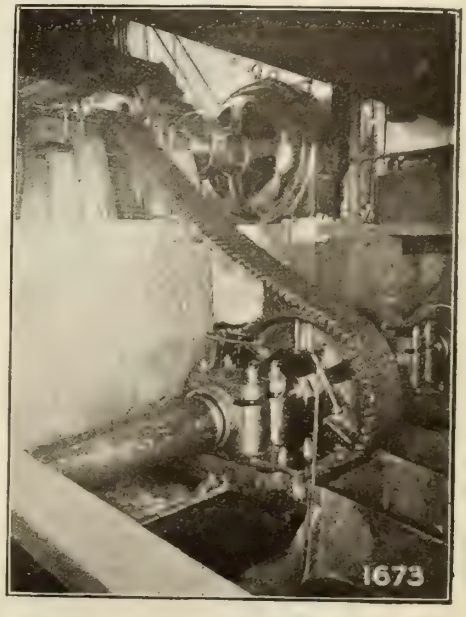
Centre Distance

For a belt drive to be efficient, there must be a long centre distance and considerable initial tension in the belt. If these conditions are not fulfilled "slip" takes place. To maintain the initial tension in the belt, constant attention must be paid to mending and adjusting the belts to remove any slackness that develops. In the chain drive, a long centre distance is unnecessary so that space can be economised. The initial tension required by the belt drive results in considerable pressure being put on the bearings with a consequent dissipation of energy in bearing friction. The chain drive being positive in action, has no tendency to slip and requires no initial tension consequently the pressure on the bearing is minimised and bearing friction and wear, due to initial tension, is eliminated. with a consequent saving of power. The "slip" in a belt is frequently claimed as a feature in favor of belt driving but it will be observed that the modern machine tool. whether arranged for belt or chain driving, is now fitted with some form of independent safety slipping clutch or pin shearing device. In works where the overhead shafting is already in existence, it will be more economical to substitute a long belt drive by means of a chain drive of similar length. While the long chain drive will give quite satisfactory results it should only be adopted where existing circumstances have to be met. A short drive, of course, effects a saving in the length of chain required and with this end in view when planning new works the countershafting for chain driving should be arranged close to the ground or even underground.

For transmitting equal horsepowers at the same speed a comparison of the space occupied in a lineshaft to countershaft, or countershaft to machine drive by pulleys and belt, and sprocket wheels and chain shows considerably in favor of the small sprocket wheels and narrow chain. The draught and danger created by wide and heavy belts and the daylight that is lost, are disadvantages of the belt drive which are greatly reduced in chain driving. to the benefit of the workmen.

Speed Reduction

The chain drive is frequently introduced to give a speed reduction which would be too large for a satisfactory belt drive and where the centre distances are too large for ordinary gearing. While possessing some of the adaptability of belts in relation to centres, chains are as positive as spur gears in their action. For this reason they are successfully employed for timed operations at fixed speeds and gear ratios such as required by various types of



Driving Large Mill Shaft.

indicators, governor drives, as used in haulage, textile and printing machinery. The positive and regular running of the chain against the "slip" of a belt or the "jar" of worn gearing ensures a better finish on the work and a regularity of output especially desirable on repetition work, due to the maintenance of feed. The cutting tool edge has a longer life with consequent saving of tool grinding and setting times. This means increased output and reduction in the power and tools consumed.

At short centre distances, the efficiency of the chain drive is maintained against the decreasing efficiency of ordinary gears due to the engagement of the chain on several teeth of the sprocket wheels giving a smooth, even turning action against the limited tooth engagement of the gear wheels, which result in wear and loss of efficiency. Frequently a gear train comprising several intermediates is displaced by a single chain drive. Under average conditions the frictional losses of a chain drive are only 2 per cent. and these do not materially increase during the life of the chain.

Silent Running

The chain drive is comparatively silent in action if run within the normal speed, and conditions of unusual heat and moisture do not affect it to the same extent as belting. Hence their frequent employment in driving oil pumps and the machinery in dyeworks, laundries and for the machinery in rolling mills and forges. Coupling with the numerous advantages stated above, the fact of the durability of the chain drive, its accessibility and simplicity of erection and that it requires little attention except for occasional lubrication, leads one to the conclusion that the chain drive can justly claim to be the most economical form of power transmission.

The two principal types of chains are: (1) the roller brush chain, (2) the inverted tooth chain. The nature of the drive and the speed at which the chain runs are the chief determining factors in the adoption of either of these types. As in the ordinary lifting chain the strength of the chain is determined by the weakest link, so it is in the driving chain. And as each link is made up of several components the failure of one of these components will determine the life of the link and the chain. Hence it will be understood that great care has to be exercised in the choice of material employed and in the gauging for accuracy and testing and inspection during construction.

The roller bush chain comprises a series of plates, rollers, bushes and rivets arranged in inner and outer links. The outer link embodies two plates and two rivets, while the inner link is made up of two plates, two bushes and two rollers.

The inverted tooth chain comprises a series of flat plates having angular projections, ground to 60 deg. angles which form the driving faces of the chain. (An angle of 75 deg. is adopted in special cases). The plates are fitted with bushes which in turn are mounted on the rivets.

Selection of a Chain

High tensile steel is employed for the plates in both these chains. They are designed to give at the weakest point a strength proportional to that of the rivets. The bearing pressure and wearing area of a rivet determines the selection of a chain for a particular job, as the life and strength of a chain depends on the area and surface condition of the rivet. Nickel steel rods are used for the manufacture of the rivets, which are hardened and ground and securely fastened to the outer links in the roller chain, as movement in the links would cause rapid wear. The bushes which are provided give a full length bearing to the rivet internally, while the external surface bears the rollers in the roller chain and the plates in the inverted tooth type of chain are held together by steel rods case hardened all over and secured to the inner links in the roller chain. The rollers which complete the inner link used in the roller bush chain are free to revolve on the bush just described. The object of the roller is to minimise friction and the consequent wear between the chain and the wheel which would otherwise occur as the chain moves on and off of the wheel teeth. A special grade of mild steel is employed for the rollers which are case hardened all over.

Tests for Hardness

Tests are made on the plates for hardness (Brinell), elastic limits, elongation, breaking load, area reduction and bursting tests at the piercings. The rivets are submitted to tests for surface hardness, impact test (Izod) for resistance to shock, shearing strain at the shoulders, measurement and microscopic examination of the core and hardened case. The bushes and rollers are tested for surface hardening and microscopically examined after case hardening. The rollers have an additional test for the crushing strains, which the roller receives when engaging the wheel teeth.

The inverted tooth chain, in which the chain lies flat on the top of the teeth like a belt, is frequently known as the "silent chain." In the roller type, the sprocket teeth project through the chain, the load being from one tooth to another as each link engages which causes the click associated with the roller chain. In the inverted tooth chain, the load is divided up on either sprocket among the full number of teeth in mesh. With the inverted tooth, as the chain elongates in pitch it assumes a greater pitch circle on the sprocket teeth, which means during the entire life of the chain each link in mesh on the sprocket teeth continues to take its full share of the load. The chain is relatively silent compared with the roller chain or spur gear.

Rocker Joint Chain

The rocker joint chain drive has an inverted tooth chain in which the joints have a non-sliding action. These are not of circular form but of a special section, and for them increased efficiency, increased durability, higher permissible speeds and less dependence on lubrication is claimed. There are two hardened steel pins of special section, one called the rocker and the other the seat pin. The former rocks or rolls on the flat surface of the seat pin when the particular section is coming into or going out of engagement with the sprocket teeth. So that there is no friction caused by sliding surfaces but simply the rocking action. When the load is on the joint, viz, while the chain section containing it is between the wheels, a broad flat bearing is presented, no load being taken on the knife edge. A parallel is sometimes drawn between the action of the ball or roller bearing and the ordinary journal bearing in comparison with the sliding joint and the rocker joint. Reducing wear to a minimum at this vital part of the chain, wear being the determining factor in the life of the chain, gives increased durability and longer life to the chain. The absence of sliding friction enables a high mechanical efficiency to be maintained with light or heavy loads while oil bath and oil-tight gear cases or other lavish lubrication is not imperative; an advantage where high speeds are employed and the lubricant is thrown off by centrifugal action. A thick grease applied to the teeth chain and wheel periodically will afford all the necessary lubrication.

Small chain wheels are usually made from mild steel blanks machined all over and having case hardened teeth. The large wheels may be of cast iron, though steel castings or stampings may be adopted if lightness is a consideration. The teeth are machine cut, the tooth shape being designed to suit the action of the chain.

To Be Continued

PIPE SUPPORT FOR MOTOR

The adaptability of individual motor drive for machine tools is well demonstrated by the conversion of a group-driven installation in an East Springfield, Mass., factory. A variety of motor mountings were necessary in fitting up this plant for its conversion from the group-drive installation, which had been used for producing rifles for war service, to individual motor drives. A Garvin No. 2 hand-screw machine, belt-driven, was connected to a 1-hp., 440-volt induction motor. The motor is mounted directly on a heavy wooden base bolted to a pipe flange at the top of the 3-inch supporting pipe which is set in the floor. The starting switch is attached to the wooden base by ¼-in by 1-in. iron straps. The arrangement carries both motor and starting switch above the machine and behind it, keeping the switch, however, within easy reach of the operator at his post in front of the machine. The motor is high enough to give a belt long enough for smooth running.

Industry Reveals Many Interesting Sidelights

How Canadians Rushed Repairs on Ocean Liner—Guelph Concern Holds Its Men—Expensive Machines Sold for Junk—Little "Hen." Thornton Now Heads C.N.R.—Growth in Auto-stamping

GUELPH'S thirty-five-year-old industry, James Steele, Limited, boasts a working force in which the so-called labor turnover is practically nil. The individual service record ranges from three to thirty-five years. One of the employees, William Gould, was with the late James Steele as a boy when the business of spring manufacturing was first established in Guelph thirty-five years ago. Mr. Gould now has charge of the upholstery spring department. Probably one explanation of staff permanency is the bonus system employed by the company. This has been in use for some years and in good times has been the means of adding materially to employees' pay envelopes at the end of each month. Although wages advanced during the war period, these have not been reduced. The company reports business to be in a fairly prosperous condition at the present time, and that the demand for springs represents a great variety of purposes. The amount of wire used during the year is from 500 to 600 tons and this includes all kinds of wire from 23/1,000, such as used in fuse plugs, to ⅜ inch, employed in machine tools. The officers of the company are the three sons of the founder, J. A. Steele, manager: H. C. Steele, secretary, and J. T. Steele, superintendent.

* * * *

IN connection with the winding up of a company manufacturing a line of steel products, the liquidator is said to have been confronted with the disposal of a number of large automatic machines that had been designed for a specific purpose and in their day had been expected to revolutionize production as it was then known in that particular branch of industry. Finally, it is said, they were turned over for $25 to an employee who had given considerable assistance during the liquidation and whose services seemed to call for some recognition. He immediately called in his favorite junk dealers and accepted the best bid of $800 for the lot or $100 per machine. It is understood that the original machine, representing much experiment, the conception of an inventive genius, cost in the neighborhood of $50,000 and that each of the other seven ranged between $15,000 and $20,000. It is stated that the machines had never actually given the service for which they were designed, but were useful up to a certain point. Nevertheless, much valuable material had entered into their construction. Like so much of the shell-making equipment that was developed during the war, they found an inglorious oblivion by way of the junk dealer.

ONE of the large liners plying between European ports and Montreal had the misfortune recently to run aground in the St. Lawrence. She was soon released and docked at one of the large docks on the river. On a Thursday evening it was found that a number of large plates were damaged and would have to be replaced. A well known firm in Montreal was called on the phone and asked to procure about twenty plates ⅞ in. thick, by twenty feet long, by six feet wide. Phone calls all over Canada and the adjoining points in the States failed to locate the plates. Friday afternoon late, definite dimensions, and the number of plates required were phoned to the steel merchants. They in turned phoned a steel mill 19 miles outside Philadelphia and over the long distance wire prevailed upon the mill to roll these plates to special order on Saturday morning. Sunday and Monday morning were occupied by submitting the steel to the two score physical and chemical tests required by Lloyds for A No. 1 classification.

Meanwhile the steamship company had, in conjunction with the steel merchants arranged with the Pennsylvania Railway System to have a car ready to load the steel and a special locomotive to pull it into Philadelphia. The steel plates constituted a full carload lot. The car of plates left the steel mill early Monday afternoon, and as soon as they reached Philadelphia, were put on a through train to New York. Here the car was handed over to the Delaware and Hudson Railway who were induced to give the car special dispatch. The car arrived in Montreal at noon on Wednesday and was handed over to the Canadian National, who were able to switch the car into the drydock siding very early Thursday morning. The old plates had been removed, and were used as templates to lay off the new plates. Drilling and punching of holes, shearing, etc., commenced at once and the plates were being rivetted on Friday.

This constitutes a record of its kind, and it was put through by Canadians. This service cost much less than express and was quite as rapid, if not more so. The estimated daily loss to the liner was $5000.00 which goes to show the urgency of the situation.

* * * *

MAJOR-General Sir Henry Worth Thornton, K. B. E., the new head of the Canadian National railroads, did not reach his present eminence in the railroad world by easy stages. He knows something about the application necessary in preliminary training, for his first experience with work, on graduating from Pennsylvania University, was in 1896 when he became a draftsman with the Pennsylvania road. Through the hard routine of engineering duties he progressed until in 1901, he took his first real executive job as superintendent of the Cleveland, Akron and Columbus railroad. Previous to going to England in 1914, he was superintendent of the Long Island Railroad and became known as a rising man in the railroad field. He confronted some prejudice when he became general manager of the Great Eastern, for in England it has always been regarded as hardly proper to import heads for institutions of long standing. Some unkind things were said directly and through the press, but Thornton accepted the proposition with courage and common sense and gradually won public confidence. This was in a year when an urgent call for big men developed in England, and while Thornton was not honored with a place on the executive committee of railroad managers to handle war traffic, the head of the Great Eastern carried on by doing his best to speed men and munitions to France. Finally, he was included in the control committee and gradually involved in a most intensive way with war transportation matters. He became director of Channel transports, and the name of Thornton became prominent where a few months previously there were those who had predicted an inglorious future. Then the King made him a Knight Commander of the Empire and, militarily, he became Major-General.

Sir Henry Worth Thornton is described as "a typical product of the American railway school. In appearance he is a big, powerful figure, something like six feet, four inches tall, weighing around 225 with level gray eyes, a close mouth and an intensive air." His experiences have brought him in contact with the long and short haul systems prevailing in America and the Old Country; he is an authority on electrification and on the application of ball bearings to rolling stock. Back in Logansport, Indiana, his old home town, thre are those who still speak of "little Hen" who wanted to be a bishop, but became a railway man instead. Opinion seems agreed that to the Canadian National lines will be the gain by reason of his concentrating on terrestrial rather than celestial methods of transport.

* * * *

THERE are certain industries which reflect or are dependent upon the development in another industry, and perhaps this is more strikingly true of motor car manufacture than of any that

(Continued on page 31)

Adapting the Engine Lathe to Quantity Production

Special Attachments to Facilitate Output—Interchangeable Tool Blocks—Individual Tool Holders Used in Groups—Adjustable Stops Assure Accuracy—Wide Range of Work

REGARDLESS of the product, every manufacturer must put in a certain amount of study to determine the most economical methods of production. The nature of the various operations that are to be performed are the governing factors in the selection of the necessary tools and machining equipment. One machine may prove ideal for one class of work but not efficient on another and it is necessary to acquire one or more machines to perform the different operations. However, if sufficient work is not available to maintain constant working of all or the majority of the machines the overhead expense is often considerable.

In selecting a machine for general purpose work it is well to choose one that has a wide range of application, one that can be used to advantage on quantity production and yet retain its simplicity for general jobbing and repair work. One of the most serviceable methods to accomplish this end has been through the use of attachments especially designed to fulfill a particular purpose. This has proven to be one of the simplest and least expensive ways of securing increased engine lathe efficiency.

Fig. 1 shows a sketch of a piece finished on the manufacturing lathe. This piece is made from .15—.25 carbon machine steel and requires two settings to complete. It will be seen from Fig. 2 that the machining is performed in two stages, the left hand view taking care of the heavy turning and the finishing accomplished as shown at the right. These two views illustrate the varied type of tool holders that may be interchanged to conform to the character of the work being performed. In the first view the single tool holder is fixed on the compound rest, while at the rear is secured a single purpose quadruple holder with the slots located at fixed distances for that particular operation, that of facing the four shoulders of the two collars. In the other view a turret tool holder is located on the front compound rest while two individual tool holders are secured on the rear rest. These may be used in any position and tools of any desired shape may be inserted. This saves a great deal of time.

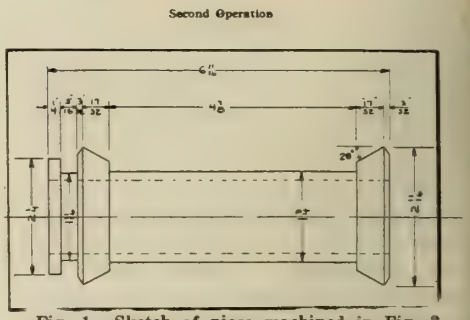


Fig. 1.—Sketch of piece machined in Fig. 2.

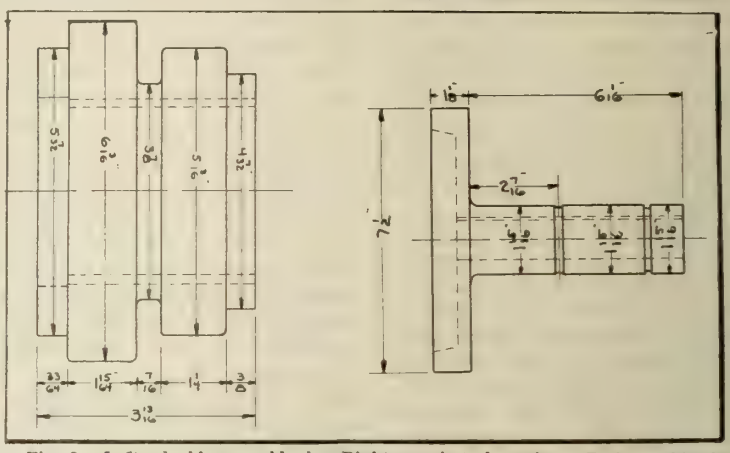

Fig. 3.—Left: double gear blank. Right: semi-steel casting. Both machined on manufacturing lathe.

The rear slide carries a plain rest coupled to the base of the cross slide. The rear rest is secured to its base by means of bolts and tee-slots which permits of adjustment to various diameters of work. The entire rear rest may be detached if desired.

Adjustable stops are provided on a bar located beneath the apron carriage for automatically tripping the power feed at any desired point. A slight pressure by hand on the hand feed wheel brings the stop bar against a fixed, solid stop, thus assuring accuracy.

In Fig. 1 the front tool turns the central portion to 1¾ in. dia. and at the finishing point the cross feed screw is reversed until the four rear tools perform their work in facing the shoulders. In the next operation the broad nose tool in the turret finishes the 2¼ in. collar on the left, at the same time making the short bevel. The second tool in turret is brought into position to finish the three recesses and then the outside bevel at right is made with third turret tool. The inside bevel of collars are turned simultaneously with rear tools.

Fig. 3 (left) shows a dimensioned sketch of a double gear blank, made of low carbon chrome nickel steel, machined on the manufacturing lathe. The turning of the main diameters is accomplished by the turret tool shown in working position. The centre groove is roughed and finished by 2nd and 3rd turret tools; facing and rear diameter turned by two rear tools. Corners are rounded by 4th turret tool. The various diameters are accurately determined by the action of the twelve stops mounted on the cross feed screw directly back of the cross feed handle. Six adjustable stops are provided for both the front and rear tools. The barrel carrying these stops is rotated by hand, bringing

the respective stop screws into line for engagement. These pieces are completed in 12 min. each. It might be mentioned that the hole is bored and one end faced at a previous operation. The work here described is that done on the special arbors.

To the right of Fig. 3 is shown a semi-steel casting, turned, faced, necked, corners rounded, grooved and rough turned, and these operations may be performed on as many pieces as desired with one setting of the tools. The turning of the shank and large diameter is done with 1st turret tool; rear facing and inside taper made with the other turret tool. Facing and grooving performed with rear tools, all of whi are held in individual and adjustable tool blocks. The complete time required to finish this piece is 11 minutes. A plan view of these two jobs is illustrated in Fig. 4.

The possibilities of shaft work are shown in Fig. 5. The top view is a piece of .15—.25 carbon, 1½ per cent. nickel steel shaft made from stock 10 15/16 in. long, 1⅝ in. diameter, completed in 7 minutes. The lower is a piece of similar grade steel made from 2⅛ in. dia. stock, finished from rough in 19 minutes.

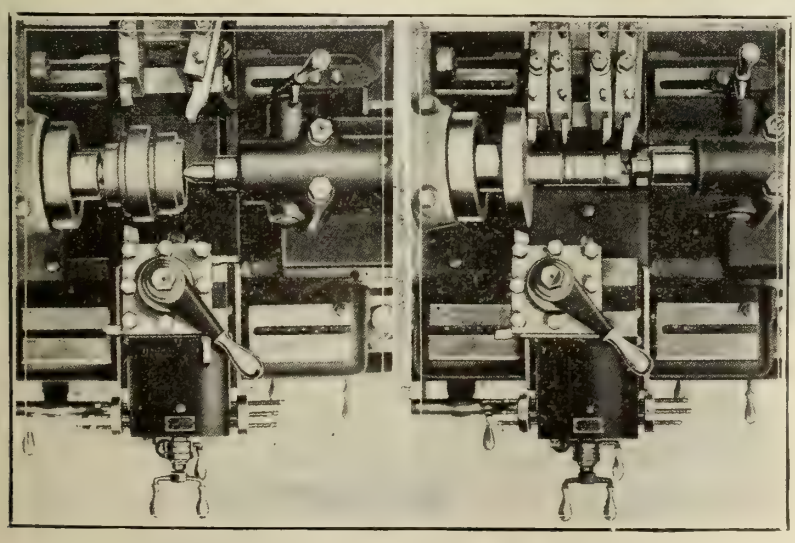

Fig. 4.—Plan view of machining on pieces shown in Fig. 3.

PAINTING MACHINERY BY THE SPRAY METHOD

A LARGE number of manufacturers throughout the country have adopted the spray gun as a method of applying fillers, paints and varnishes to their products. Their choice in this matter has been determined on account of the fact that the use of the spray gun saves them actual time and money in the matter of applying finishes to their products and it also insures uniformity of coating and quality of the product.

In a plant manufacturing oil engines the spray gun is used to great advantage for applying heavy fillers to engine castings. For this service a spray gun of the pressure type with a comparatively large nozzle opening is used for spraying filler in semi-paste form. This filler is driven into the pores of the iron by the impact and air pressure and is applied in a smooth, even way that requires very little sanding to render the surface fit to receive the second enamel coat. The enamel coat on this engine job consists of an oil proof high gloss enamel. This enamel is sprayed on with a pressure type spray gun, the spray head of which is adjustable so that either a round or flat spray can be produced. With this spray gun the operator is able to reach parts of the engine that are inaccessible to a paint brush and the time and labor saved is at least 75 per cent. less than when the hand brush was employed to do the same work.

In the washing machine industry the spray gun plays a very important part. Modern washing machine parts in a disassembled state are sprayed with a rust preventative color coat, the parts are then assembled and the completed machine is given a final coat of finishing enamel.

The manufacturer of a line of art metal cabinets is employing the spray gun in the finishing of his product. All of the cabinets and articles produced by this firm have a new metallic stippled and blended finish. This is highly ornamental. For instance, a cabinet is sprayed with a dark copper bronze with a completely hiding coat. Over this is sprayed at very low air pressure a light stipple of vermillion. Next a heavy stipple of black and then comes a light stipple of white. The finishing coat consists of a clear varnish. When the job is finished the result is a very beautiful blended metallic surface that is exclusive and different from other finishes usually found on products of this kind.

At the plant of a large manufacturer of lifting cranes all of the painting work is done with pressure type spray guns connected to paint tanks. The structural iron part of the crane as well as the cast iron and machine parts are given, first, a coat of heavy red lead, and, second, a black bitumastic coating. All of this work is done in the yard after the crane has been assembled for a test, and the saving over other methods of applying paint that this company have been able to accomplish is enormous.

One of the large manufacturers of steam engines and electric generators employs the spray gun for applying all paints and finishes to their products. The insulating paints that are used on the coils and rotor of the generators is sprayed on with a cup type spray gun. This finish consists either of shellac or special dielectric paints; on the generator castings a heavy filler is first sprayed on and when dry sanded out. Over this is sprayed a heavy coat of gray enamel. The same materials, with the exception of the insulating varnishes, are also sprayed on engine castings in this factory, and when it is necessary for this company to assume the erection of a complete power plant a spray gun equipment is always shipped out to the job and is used for applying paints to engine foundations, floors, walls, boilers, piping and buildings.

In almost every plant manufacturing machinery and where the product is to be treated with a liquid finishing material the spray gun has a distinct place and it will cut down the time and labor in getting out the work and will often save paint.

Practical Ideas From Practical Men

CALCULATING THE STIFFNESS OF SHAFTS

By F. A. Livermore, A.M.I.M.E.

Calculating the angle of twist in a shaft is not an every day requirement and, consequently, when the time arrives, we find ourselves hazy on the necessary formulas for the calculation. All goes well with the general formula until we are faced with the torsional modulus of elasticity and in the resulting answer we are doubtful as to the correctitude of the angle of twist. To avoid any confusion, I am substituting a simplified formula and a table of values from which the angle of twist can be readily obtained. First, I reiterate the old theorem:—the torsion or twisting moment is equal to the twisting force times the lever arm about which it acts.

From any mechanical handbook we can obtain the formula—

$$D = 585\ PRL\ Gd^4$$

Let

D = the twist or deflection in degrees.

R = the radius of the twisting force in inches.

L = the length between the arms of twist.

G = the torsional modulus of elasticity.

d = the diameter of shaft in inches.

P = the twisting force in pounds.

S = the shear stress in pounds per square inch.

With the degree of the angle of twist, the resulting stress created is:—

(a) $$S = \frac{DGd \times 57.3L}{2}$$

Simplified down gives $$\frac{140{,}700\ Dd}{L}$$

The problem as it is usually stated is to determine what diameter shaft will maintain the twisting moment below a certain required limit; to ascertain this we proceed as follows:—

By transposing in (a) and solving for "d" we have—

(b) $$d = \sqrt[4]{\frac{585\ PRL}{GD}}$$

Since the torsional modulus of elasticity is approximately 12,000,000 lbs. per sq. in. for steel, substituting this value in (b) it reduces to—

(c) $$d = \sqrt[4]{\frac{PRL}{20{,}500\ D}}$$

By further simplification of (c) we get—

(d) $$d = \sqrt[4]{\frac{PRL \times 0.835}{D}}$$

Since the angle of twist shall not exceed a certain value, the equation (d) can be brought to its simplest form as—

(e) $$d = K \sqrt[4]{PRL}$$

Where the value of "K" is obtained from the expression—

$$K = \sqrt[4]{\frac{1}{D}}$$

The following table by J. S. Carpenter (mechanical handbook) gives the values of "K" for corresponding values of "D"; all that is necessary is to find the nearest value of "K" and substitute for solution in the equation (e).

Tables of Values of "K"

D	K	D	K	D	K
.25	0.1180	2.50	0.0665	5.50	0.0545
.50	0.0991	3.00	0.0635	6.00	0.0534
.75	0.0896	3.50	0.0612	7.00	0.0514
1.00	0.0835	4.00	0.0591	8.00	0.0497
1.50	0.0755	4.50	0.574	9.00	0.0482
2.00	0.0703	5.00	0.0558	10.00	0.0470

So to find the angle of twist or deflection of a given shaft, the value of "K" is found from

$$K = \frac{d^4}{PRL}$$

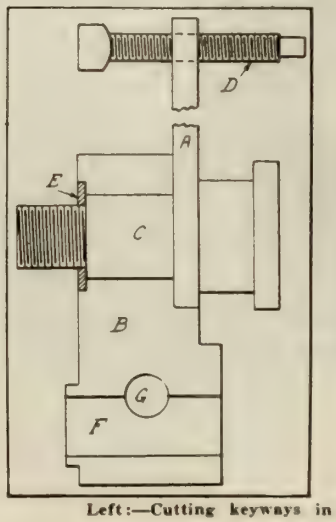
and by referring to the table a result can be obtained which is accurate enough for all practical purposes.

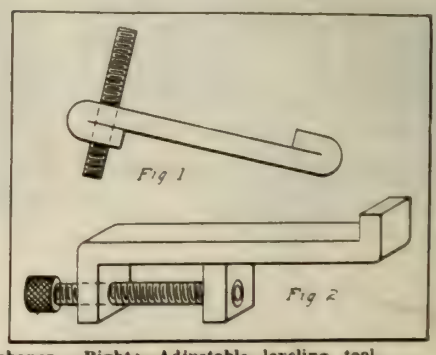
ADJUSTABLE LEVELING TOOL

By Harry Moore

The adjustable leveling tool shown here was devised to facilitate the manufacture of a large number of wedge shape blocks to be used on the ends of slides. Milled at an angle on one end only and this angle varying with different batches, it was necessary to have an adjustable feature on the tool required to hold them, in order to keep the top parallel with the surface plate and drill press table when marking off and drilling. Blocks of this kind are frequently used in the construction of built-up jigs, fixtures, etc., and perhaps the description of the tool used to hold this particular lot will be of interest to others.

Fig. 1 shows the tool as first made up: This consists merely of a piece of ¾ in. x ¼ in. stock bent over close at opposite sides on both ends. One end is tapped for a stud by means of which the angle of the tool is changed to suit the work. Although very simple to make, this holder, in some cases, was not quite satisfactory because of the projecting screw interfering with the work. A better device is shown at Fig. 2 and this was the one generally used. This also is made of ¾ in. x ¼ in. stock, both ends being bent at right angles in opposite directions. One end A is tapped for a ¼ in. knurled head screw B which carries at the end a square block C, the end of the screw being turned down and riveted over lightly for the purpose. By adjusting screw B in or out the angle of the tool can be changed to suit the work as desired. It is solid enough to hold work when being drilled with light holes in addition to being used for laying out as shown in the illustration. There are of course many ways in which this work could be done, but as a quick method for leveling up the top faces for the light operations noted this tool has proved all that could be desired.





Left:—Cutting keyways in shaper. Right:—Adjustable leveling tool.

CUTTING KEYWAYS IN SHAPER

By William Garnham

The accompanying sketch illustrates a simple but useful attachment for placing on a shaper when cutting keyways or tee-slots, or on work where it is desired to have a more rigid clamping of the tool. The special block A for supporting the tool bar is cut away at the back to receive the plate A which is firmly secured in position by means of the bolt C. The cutter bar is locked in position by the tapered pin G. The long set screw D is forced against the vertical slide, thus preventing tool chatter.

Acceleration a Factor in Cam Layouts

By John S. Watts

THE mast common form of cam is known as the heart shaped cam, designed to give the follower a uniform velocity throughout its travel. The only advantage of this type is that it is simple to layout, but it has serious disadvantages in that it is inefficient and noisy. The fault in this design of cam is that it attempts to start the follower from a state of rest to its maximum velocity instantly, I say attempts advisedly, as although the cam is made to do this very thing, the power required to do it is infinite, and is hence impossible. The actual result being that some part of the mechanism upon which the cam acts has to give or spring enough to cushion the blow and allow the mechanism to acquire velocity more or less gradually. It is only by reason of the relatively low speeds and short travels of the followers that such cams do not fail immediately. The idea that a cam can start its follower off instantly at full speed is as fallacious as would be the attempt to start a heavy train off at its full speed, from which it differs only in the weights involved, the force required being infinite in both cases. In practice the men assembling such a cam will find it working hard, and ease it off by filing the starting part of the cam surface, until the action is made bearable, but this is nothing more than a palliation of the evil, and a cam properly designed will need no such tinkering to make it work smoothly.

A later form of cam is designed to give the follower a uniform acceleration during the first half of its stroke, and a uniform deceleration during the latter half, which is a decided improvement upon the uniform velocity type, but is still short of perfection inasmuch as there is normally no valid reason, except possibly a slightly simpler layout, why the periods of acceleration and deceleration should be equal. On the other hand as the power required to accelerate a body to a given velocity, varies inversely as the time taken to acquire this velocity, it is clear that the longer we can make this period of acceleration, the lower will be the force required. Then again in the average run of cam mechanisms, the resistance against which the cam is working is much more than can be overcome by the inertia of the follower and its rods and other moving parts or in other words, the conditions are such that the follower will come to rest immediately the cam ceases to push it forward. Under these circumstances there is no advantage gained in having any deceleration period at all. The only case which requires a period of deceleration is where the roller would leave or tend to leave the cam at the end of its strike, due to the inertia of the follower parts overcoming the resistance and making a longer travel than that which the cam imposes upon it. On this point a decision can only be made after a study of the individual case.

The ideal cam is one that gives a uniform pressure against the roller throughout its working travel, it being obvious that under this condition the pressure will be the lowest possible. To gain this we must consider all the forces against which it has to work. These are, first, the resistance due to the function of the cam, for an example, in an automatic machine tool, the feeding in and out of the cutting tool, or in a gas engine, the lifting of the valves. Second, the acceleration of the moving parts of the follower, etc. Third, the friction of the moving parts.

Generally speaking the first and third forces are uniform throughout the working stroke, and cannot be reduced by any alteration in the form of the cam. The second force, that of acceleration is determined entirely by the shape of the cam, and can be made uniform, or in cases where the first force varies during the stroke, the accelerating force can be varied to be higher when the functioning force is low, and vice versa, to make the total force exerted by the cam uniform during the stroke.

To compare the difference in efficiency between the three types of cams, we will work out the force required for acceleration for each type. As said before the force required for the first type of cam, the uniform velocity type, will be infinite. For the second type, having a uniform acceleration, during the first half of the stroke, the force of acceleration is given by the formula

$$f = \frac{WV}{gT}$$

Where f = force of acceleration in pounds.
W = weight of moving parts in pounds.
V = maximum velocity in feet per second.
T = time in seconds taken to acquire the velocity V.

For purposes of comparison we will take W to be one, the stroke of the cam to be two inches, and the time taken to execute one stroke to be two seconds. As the maximum velocity is attained at one half of the stroke, the space S, travelled through in attaining the maximum velocity from rest, will be one inch, and the time taken in traversing S will be one second. The maximum velocity attained will be found by the formula,

$$V = \frac{2S}{T} = \frac{2 \times 1}{1} = 2$$

Substituting in the formula,

$$f = \frac{WV}{gT}$$

we get $f = \frac{1 \times 2}{32.2 \times 1} = \frac{2}{32.2}$

Making similar calculations for the third type, having the acceleration period last throughout the whole stroke, we get S = 2 and T = 2.

Therefore $V = \frac{2S}{T} = \frac{2 \times 2}{2} = 2$

That is, the maximum velocity is the same in both cases, but in this third type the time of acceleration T is two seconds instead of one as in the second type and the formula gives

$$f = \frac{WV}{gT} = \frac{1 \times 2}{32.2 \times 2} = \frac{1}{32.2}$$

or a force just one half of that required for the previous type of cam.

To lay out a cam for uniform acceleration rising in one half of a revolution of the cam, proceed as follows. The space travelled during succeeding units of time will be 1, 3, 5, 7, 9, etc. Referring to figure herewith, the distance ab, being the total travel of the cam roller, and using six divisions of the stroke, we have as the travel during each division 1, 3, 5, 7, 9, 11 parts of the total stroke respectively. Adding these together we get 36 parts, and dividing ab into this number of parts we draw circles through the points number 1, 4, 9, 16, 25 and 36 to meet their respective radial lines, the intersections giving the centres of the roller, and the curve can be drawn in the usual way.

If it is desired to have the velocity decrease during the latter part of the stroke, this can be done by a similar process, the deceleration period being laid off to give a travel during successive periods on the same order as the acceleration period, but reversed as 11, 9, 7, 5, 3, 1. The deceleration period being made any desired part of the stroke, as say one-sixth, to meet the particular condition.

The return stroke can be made to suit any conditions, but generally speaking with a follower returned by gravity or spring pressure a uniform velocity curve is most satisfactory. If the cam roller is actuated positively by the cam during the return stroke, the uniform acceleration curve is best with, under certain conditions as outlined before, a part of the stroke for deceleration.

CAST IRON SPLIT PULLEY

An interesting design of cast iron split pulley has recently been developed by Messrs. John Jardine of Nottingham, England. It is made in two pieces in such a way that lugs on the smaller part are forced against shoulders of the main portion by means of a heavy set screw, and giving a three-point bearing on the shaft. Small variations in shaft diameter do not affect the grip to any extent. Its construction permits of placing on shaft close to a bearing or between pulleys where difficulty would be experienced when using a spanner.

New Things in Shop Equipment

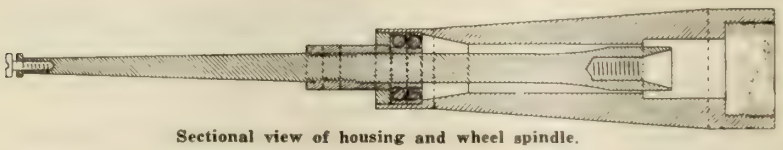
FLEXIBLE-SHAFT OUTFIT

An outfit especially intended for driving screws, as in the manufacture of radio equipment and similar apparatus, has been developed and placed on the market. It is arranged for overhead mounting but may be fixed to a bench or wall if desired. The countershaft is equipped with tight and loose pulleys, and a lever-operated belt shifter. The drive from the countershaft to the flexible shaft pulley is through a round leather belt. For high speed work the device is fitted with ball bearings. Special shafts and finder sleeves can be provided to suit the work being performed. These devices are made by the Hergi Mfg. Co., Bridgeport, Conn.

EXTENSION HOUSING AND GRINDING SPINDLE

An attachment for multi-graduated precision thread grinders, intended for deep internal grinding to a depth of 12 in. on holes 2 in. in dia. or greater, and a depth of 6 in. on ½ in. holes, has been placed on the market recently. It is particularly applicable to the operation of grinding the tapered bore in milling machine spindle; perfect concentricity of this bore promotes full service and long life of cutters especially in cases of unhardened milling machine spindles, which are subject to scoring and wear. The use of this grinder with the extension spindle speedily corrects the fault; increases efficiency and production. An untrue running cutter dulls rapidly on the few teeth that do the burden of work and soon chatters and proves unsatisfactory. Lathe spindle tapered bores also require trueing occasionally to correct errors in concentricity and alignment, obviating the necessity of trueing centres each time lathe is to be used on accurate work.

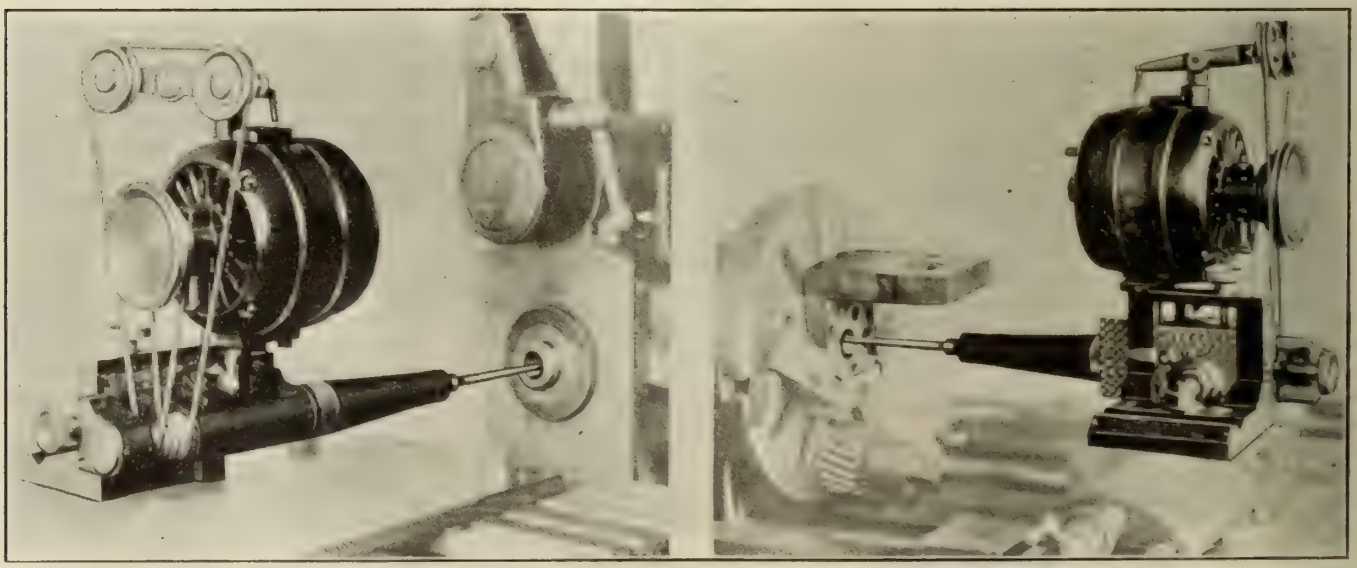
The extension spindle is particularly serviceable for grinding holes in pieces where projecting arms make it difficult to grind with short range outfits. To the right of Fig. 1, it shows the machine grinding a hole in a hardened fixtur Fig. 2 shows the line drawing of the spindle and housing. The extension housing is screwed on the projection threads on front regular spindle cap. This makes an accurate and speedy attachment. The extension spindle couples on to the regular spindle by the tapered fitting joints, and is supported at working end of radial and end thrust ball bearing at extreme end of extension housing. The great length of spindle support produces rigidity at grinding end of spindle. Simplicity, speed and accuracy of attachment to grinder together with great range of work, makes this an indispensable auxiliary attachment to every multi-graduated precision grinder. This device is manufactured by the Precision and Thread Grinder Mfg. Co., Philadelphia, Pa.



Sectional view of housing and wheel spindle.

LARGE ROLL GRINDING MACHINE

A heavy-duty cylindrical grinding machine especially built for finishing all types of hot and cold mill rolls has been placed on the market recently. The tool is self-contained and is operated by three separate motors. One motor which is directly connected to the headstock is used for driving the work; another is mounted on the grinding wheel carriage for driving the grinding wheel. The third motor is used for operating the water pump. The operator controls all of these motors by means of push buttons located in a convenient position on the operating platform. This platform is part of the grinding wheel carriage, so that the operator has a clear view of the point of contact at all times. All gears are made of chrome-nickel steel and operated in oil baths. The wheel carriage is driven by means of a worm and rack, and provision is made for a brief period of tarry at the point of reversal. Facilities are also provided for rapidly moving the wheel to and away from the work. A special feature in construction is an attachment for grinding the periphery of the roll either concave, convex, or straight, as desired. The amount of curvature is controlled by a simple system of gearing at the back of the machine. The roll supports furnished with this machine are of the two-bearing type, which allows of grinding the journal without changing the roll position; this keeps journal concentric with body of roll. These machines are built in three standard sizes, 20, 30, and 40 in. and any desired length. They are built by the Landis Tool Co., Waynesboro, Pa.



Left—Truing up tapered bore of milling machine spindle. Right—Grinding hole in angle plate with long projection.

WALL BRACKET DRILL

A light swinging drill that can be attached to a post or wall, and that is capable of operating on holes within a radius of 3½ feet of the swivel, has recently been placed on the market. The machine is particularly applicable to light drilling up to ⅜in. dia. in steel. It is belt-driven through tight and loose pulleys, the vertical shaft being connected to countershaft by means of bevel gears. The countershaft yoke can be placed in any position to conform to location of overhead drive. The spindle is equipped with ball thrust bearings and has a movement of 2½in. The spindle quill is of steel with bushed bearings and a rack cut from the solid. Two spindle speeds are provided, 500 and 1,300 r. p. m. These drills are made by the Hammond Mfg. Co., Cleveland, Ohio.

8-INCH ELECTRIC GRINDER

A small bench grinder, carrying 8in. by ¾in. wheels, and operated by a ½ h. p. motor, has been placed on the market recently. The motor operates on either direct or alternating current at voltages of either 110 or 220. Large bearings are provided for the motor shaft which operates at a no-load speed of 3,600 r. p. m. The machine is supplied complete with two abrasive wheels, two wheel guards, two adjustable tool rests, a toggle switch in the base, and 5 ft. of electric cable fitted with an attachable plug. These machines may be mounted on a pedestal if desired. Net weight about 75 lbs. They are made by Black and Decker Mfg. Co., Baltimore, Md.

PILLAR PUNCH PRESS

A small pillar punch press primarily designed for work on radiator cells has recently been developed and placed on the market. It can readily be adapted to any class of work within its capacity. The ram has a stroke of 1¼in. with a vertical adjustment of 2in. Maximum clearance between ram face and bed is 5in. the surface of the latter being 9½ by 11in. The machine is driven by means of a 3in. belt running on an 18in. flywheel with a solid web. It requires a floor space of 36 x 40in. and weighs about 700 lbs. It is made by Geo. W. Dover, Inc., Providence, R. I.

POWER SCREW PRESS

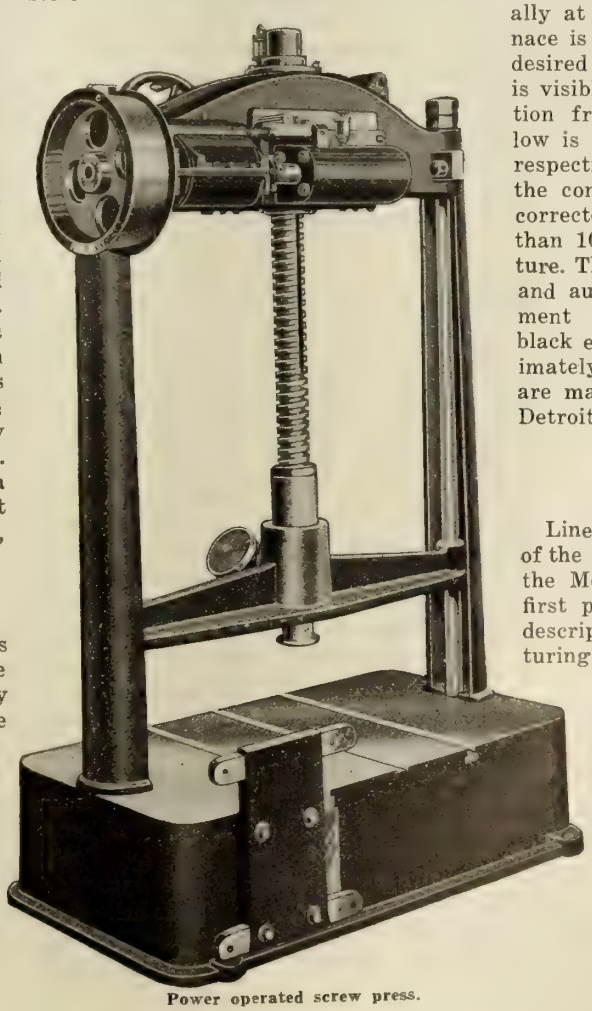
The accompanying illustration shows the cut of a screw press placed on the market recently. It is operated by means of a marine type of clutch. The engaging mechanism may be controlled either by hand-wheel shown at top of press by lever placed to suit operator. The standard size is built for 25 to 30 ton work with a ram speed of about 7 ft. per min. By changing the lead of driving worm, gear and screw, speed may be increased or decreased as desired in practically any production work, but pressure will diminish as speed is increased. Special bases or fixtures may be supplied to suit requirements and uprights of any length furnished for long work. The standard base is a perfectly planed surface with tee slots and keyways so that jigs and fixtures may be accurately fitted. A hole may be cored in the base if desired. The thrust on the screw is carried by heavy oversize S. K. F. ball thrust bearings; on worm by radial ball thrust bearings. When furnished with single thread lead screw, pressure may be held indefinitely at 25 to 30 tons. On such work the clutch is released and no power consumed. When individually driven a 5 h. p. motor operating at a speed of 1,200 r. p .m. is used. The press is 37½ in. between uprights; 32 in. clear in top position; maximum movement of ram 24 in. The screw is 1 in. pitch and 2 in. lead, 3 in. dia., and 48 in. long. The machine is 76 in. high and requires a floor space 27 in. by 48½ in. It is made by the Atlas Press Co., Kalamazoo, Mich.

CENTRELESS GRINDING MACHINE

Several changes and modifications have been made recently to this particular grinding machine. A special feature of the new design is the "drop in" attachment which makes it possible to grind either shouldered, tapered or straight work. This rest consists of a steel bar with a hardened and ground edge for supporting the work in a true horizontal position between the two grinding wheels. An extended slotted guide is located at the top of the bar, with an opening just large enough to receive the work to be ground. Side guides on the bar hold the work in the proper position between the two wheels. Adjustable stops are provided for different lengths of work, so that the grinding can be accomplished without touching the shoulder of the work.

The work rest is mounted on rollers and travels with the work. It may be drawn forward about 5 inches for insertion of the work and again moved back for grinding.

Another feature of the machine is the balanced ways and arbor for the grinding wheels, as it is essential that wheels be in fairly accurate balance. Holes are provided in the hub for the insertion of pins opposite the heavy side. Permanent balancing ways are a part of the regular equipment, these being fixed to the base of the machine. These grinders are manufactured by the Reeves Pulley Co., Columbus, Ind.



Power operated screw press.

TEMPERATURE REGULATOR

A device for automatically controlling the temperature of electric, oil or gas furnaces has been placed on the market recently. The furnace temperature can be held within a 10 deg. F. range. The control mechanism operates automatically at 30 sec. intervals. When the furnace is operating within 8 deg. F. of the desired temperature, a white signal light is visible at the top of the board. Variation from the limited range high and low is indicated by red and green lights respectively. The mechanism operates the control switch, so that the error is corrected before it has deviated more than 10 deg. from the desired temperature. The control is claimed to be positive and automatic. The case of the instrument is made of cast iron and has a black enamel finish. It weighs approximately 27 pounds. These regulators are made by the Hoskins Mfg. Co., Detroit, Mich.

CATALOGUES

Line Shafting Equipment is the title of the latest catalogue, No. 43, issued by the Medart Co. of St. Louis, Mo. The first part of the book contains a brief description of their method of manufacturing shafting, while the remainder is devoted to the listing of a wide range of products used in transmission of every character. In addition to being a catalogue, the book contains many tables and engineering data that make it very useful as a textbook.

Sale of three turret lathes by a Toronto dealer recently, is another of the many signs of improved buying tendency.

THE MACLEAN PUBLISHING COMPANY, LIMITED

143 UNIVERSITY AVENUE
TORONTO, CANADA

New Head for C. N. R.

ANNOUNCEMENT is made that Major-General Sir Henry W. Thornton, K. B. E., for eight years general manager of the Great Eastern Railway of England, has been chosen as president of Canadian National Railways. The board named to assist him is made up of representative business men whose names are not altogether familiar in railway matters, but who may bring a more practical application of actual business requirements to bear upon transportation problems in Canada. The selection suggests recognition of important sections of the country, and labor has been given consideration.

There are those who attach some political significance to the choice of board, but this is to be expected under circumstances attending practically all public appointments. One thing seems to ballast the proposition, however, and that is that the new head has a reputation based upon practical common sense, an efficiency that links up economy in operation and with unmistakable ideas as to the meaning of intensive co-operation. His task in England has brought out these characteristics and he is a man who may be expected to develop the best that is in the national system. This should mean a businesslike administration unhampered by and divorced from political influence.

Industry Has Its Risks

THAT THE man in the shop cannot always appreciate to the full what is involved in placing at his service the equipment essential to efficient production, is illustrated by the report that eight automatic machines, designed for special purchase, were recently sold for $25 and resold for junk for $800. The machines, it appears, approximated a total outlay of $150,000, the cost of the original being $50,000. Here is one instance where vast expenditure practically came to naught. This was part of the outlay necessary to launch and carry on a business. Yet it involved no responsibility on the part of the mechanics or of others employed. They were called upon to enlist only their skill in production, or in giving effect to method.

It is not by any means suggested that enterprise belongs to any one class more than another, or that one man has any more right than another to organize industrious effort in the production of goods for which there may be a ready demand, but there are those who, unthinkingly it may be, fail to appreciate the risks and responsibilities that enter into modern industry, or what vast amount of expensive experimental work may be required before an objective is reached. There are actually those who, coming from the ranks of the workingmen, have themselves experienced something of the futility of effort. Fortunately there is such a thing as success, but in many cases, it is the result of an individual application which persisted in carrying on, probably not pausing to note how small a thing is sentiment and how undependable a thing is general sympathy as encouraging factors.

Should City Pay Higher?

SHOULD municipalities buy labor at higher wage rates than private taxpaying industries are able to pay to their laborers? If so, how much? This is a question which, it is stated, will probably be a plank in the platform of economists at the next municipal election in Toronto, for it is there that the city laborer is paid 55 to 60 cents an hour, while the rate in private industry runs from 30 cents to 45 cents, and for work that is often harder and, quite as frequently, more intelligent than that performed on the city streets. Where the economists who are asking the question expect to land at the hands of the electorate is difficult to say, but at first glance they would appear to be entitled to some support from that part of the community which can never expect to appear on the city payroll or who cannot view with favor the appealing concern shown periodically for the workingman by city hall politicians.

Business men declare that the attitude of Toronto aldermen on this question seems to be hereditary or bequeathed from preceding generations of aldermen. All have had their eyes upon the workingman, while private industry has had to consider the city as a competitive factor in the labor market. It evidently makes a difference where the money comes from for no buyer of labor, whether he be alderman or not, is going to pay, as a private individual, more than the general market requires.

A prominent iron and steel concern is paying, say, thirty to thirty-five cents an hour, and would gladly pay more if they could afford it. They declare that the policy of over-liberality at the city hall has a tendency to demoralize the labor market for the immediate demand is for the same wage as that paid for city work. There are aldermen who admit that it is not the right thing, but not one has dared advocate a general change. While in other cities there is some public condemnation of over liberality in city payrolls, in Toronto approbation from a well-organized section of the community outweighs the political significance of criticism from any other section. It is not a question of the workingman's worth, or what he is entitled to. Fortunately his wages in many cases represent a higher appreciation of this service, but workingmen have a right to ask why they should be taxed to pay so much higher wages, through their representatives, than they can obtain from private industry.

Huge Tonnages Accumulate With Delivery Short

Production Speeds Up But Consumption Handicapped—Mills, However, Require Orders and Premiums Disappear—Advances in Boiler Tubes and Hoops—Good Showing in Fall Business

DECLINE PREDICTED IN PIG IRON PRICES

SOMETHING like 1,500,000 tons of steel were purchased by American railroads immediately preceding the increase in steel rails from $40 to $43 on Oct. 1. The stipulation is that the rails shall be taken out by July 1, 1923. The fact remains, however, as indicated by advices received from Pittsburgh, that the mills are still going to require orders. At present the problem has to do with shipment, as consumers want more steel than the mills can deliver. When improvement in transportation comes, with the season of lower consumption, further orders will be required.

There are conspicuous instances of accumulation due to lack of cars. The Carnegie Steel Co. has 100,000 tons of finished and semi-finished steel awaiting shipment. American Sheet and Tin Plate Co. is operating at 10 per cent. lower rate owing to shortage of supplies. Many concerns have been compelled to resort to motor trucking. Some apprehension is felt in the prospect of an early winter. In the meantime, products are piling up and costs are being swelled. This must contribute to the price stiffening that is everywhere in evidence. Unfilled tonnages for the past month will show a large increase.

On the present basis steel ingot production is at a rate of 36,000,000 tons a year, or 20 per cent. more than in 1912 and 1913, two of the biggest years before the war, while exports are smaller. Delivery premiums are disappearing, leaving the market at base prices. Already there are predictions as to the extent of declines. Bars, shapes and plates, it is said, will go to $1.75 in the next readjustment. Canadian prices range from $3.25 to $3.40, with the Hamilton mill price at $2.70. Boiler tubes are the latest to register an advance, this time it is $4 per ton, or about five per cent. on present prices. Steel hoops have also advanced slightly.

Pig iron prices, it is predicted, are due for an early decline. The prevailing spot figure for domestic pig is $39.30, which cannot compete with quotations of $36.50 and $37.75 for English and Scotch pig, on cars, at Galt, Guelph and Brantford. There is not a large quantity of import iron available, and it is likely that, with the close of St. Lawrence navigation, it may cease to be a factor on the market.

Dealers report that sales records show a falling off in small orders, but an increase in large tonnages. There is still a good demand for structural steel, but deliveries are a serious handicap. No cancellations have appeared.

Toronto

Oct. 11.

OCTOBER is displaying some indication of being a fair month in iron and steel business on Toronto markets. Buyers are evidently satisfied that nothing better in the price situation is likely to develop and recent orders, though fewer, aggregate larger tonnages. In structural steel required in bridge and building operations the record is well in advance of last year and, in spite of shipping difficulties, the demand continues. There have been no cancellations on account of slow delivery, and it would seem that problems arising in this connection have been pretty well anticipated and provision made accordingly. It is regarded as somewhat remarkable that business should maintain its strength with big buying factors, such as the railways, practically dormant, but by students of the situation this is attributed to a steady development along normal lines. If industry can hold this record without recourse to some of the larger elements, then so much the better when these again emerge from their period of seclusion. The appointment of Sir Henry Thornton as head of the C. N. R. has naturally aroused some speculation as to future buying policy. There are those who predict that the new head will take his orders from the government, while on the other hand it is declared that the country is hardly paying $50,000 a year for that kind of manager.

Pig Iron.—The situation here shows little change. Spot price is still $39.30, with supply confined largely to Algoma, producing something like 8,000 tons monthly, and to Scotch and English pig. It is stated, however, that supplies of the latter are somewhat restricted and that what quantities have accumulated represent ballast rather than full shipments. Prices on this import, however, are lower than the domestic article. In fact, as an example, buyers in Guelph report having received prices ranging from $35 to $37.50, Guelph, on this iron. This is certainly a competitive factor, and it would not be surprising to see slightly easier prices on the domestic line. The coal situation is easier and with gradual return to normal, aided materially by prevailing good weather for water shipments, the situation is bound to improve. Steel of Canada is not likely to appear for foundry business for a while. They have blown in one of their two furnaces on basic iron, but this will probably be used for steel-making purposes. No serious shortages appear to have developed among the foundries.

Iron and Steel.—Markets in this department are firm with prices ranging from $3.25 to $3.40. Hoops have advanced, and while prevailing quotations are around $4.50, it is felt by some dealers that $4.70 would better represent prevailing conditions, and in hoops, the critics observe, this price would obtain if warehouses took advantage of the spread as between mill and warehouse extras, as they do in other items such as bars. Here again is seen that lack of cohesion or agreement in the matter of prices, so characteristic of the Toronto market.

Sheets continue in good demand, but there is complaint of delayed shipments. One large concern reports the non-arrival of a big shipment of blue annealed that should have made its appearance in July. Thus quite an amount of work is being held up.

An advance of $4 per ton on boiler tubes means an increase of about five per cent. on present prices.

Scrap Metals.—Prices show a firming tendency especially on No. 1 machine but fundamentally the market shows little change, and the following average buying prices represent fairly the basis on which business is being done:—

Copper, light, per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Non-Ferrous Metals.—Speaking of the copper market an authority claims that there will be little change this year

unless, of course, war develops in Europe. It will be recalled that on the outbreak of the Great War there was a considerable break in copper owing to the menace to shipping, while for the same reason tin almost doubled in price, only to resume normal levels when it was evident that the seas would remain open. In the present case there is not likely to be a menace to shipping and for that reason price fluctuations will more accurately reflect supply and demand. There is no outstanding factor in the market at present and prices are as follows:—

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	38 50
Lead	7 00
Spelter	8 50
Antimony	8 50
Aluminum	23 00

Montreal

Oct. 11.

ALTHOUGH business on the whole continues satisfactory, it is by no means up to normal level. It is expected that from now to the close of navigation the demand for the complete range of steel products will improve and the next two months may prove very satisfactory.

Railways continue to buy only what is actually required for upkeep purposes and until they enter the market for their usual normal supplies, conditions in the steel trade will continue to be below par.

Sheet markets, in both black and galvanized, are extremely firm with indications for higher prices. This is largely due to the delay in obtaining supplies from American sources combined with a firming up of prices in the Old Country. Boiler tubes are in good demand and prices are steady. Following are prevailing prices on iron and steel:—

Iron bars, base	3 15 to	3 25
Steel bars, base	3 15 to	3 25
Reinforcing bars, base	3 15 to	3 25
Steel hoops	4 25	
Tire steel	3 25 to	3 40
Spring steel	7 00	
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes	....	3 40
Sheets, black, No. 28	....	4 40
Sheets, blue, ann., No. 10	....	4 00
Canada plates, dull, 52 sheets	....	5 50
Canada Plates, all bright	....	7 00
Galvanized Sheets, No. 28	....	6 50

Pig Iron Markets have not reflected much change in the past two or three weeks, although the general trend seems to be in the direction of more business, with a stiffening of prices. Local mills have not made any definite change within the past ten days. Algoma No. 1 foundry iron, Montreal, is now quoted at $41.65 per gross ton. Some competition has developed in English and Scotch pig which, at present, is offered at lower prices. There is a marked scarcity of import iron, however, and where consumers require quick delivery Canadian iron is being purchased. Current prices:—

Algoma, No. 1, car lots on tracks, nominal quotation	41 65	
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	40 50	....

Non-Ferrous Metals.—There has been little activity during the week in this department, although demand, it can be said, indicates industrial improvement. Reflecting American conditions, tin has advanced to $38.50. The coppers are stationary. Local prices:—

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	36 00
Lead	7 25
Spelter	9 00
Antimony	6 75
Aluminum	22 00

Pittsburgh

October 11, 1922.

IN THE recent rail buying movement, produced by the rail mills announcing an advance in price from $40 to $43, effective October 1, and proposing to enter orders previously at the old price, considerably more than 1,000,000 tons was secured by the mills, while at the same time there was heavy buying of joints, spikes and tie plates. The total of all this business is estimated at about 1,500,000 tons. The object of the mills in making this offer was to secure winter and spring rollings, there being a stipulation that the rail should all be taken out by July 1, 1923.

At the time the offer was made, about a month ago, it did not appear particularly probable that the steel mills would stand in need of orders in the winter, and some surprise was expressed at the offer on that account. It was clear that the price advance was justified by circumstances, as the $40 price seemed somewhat low a year ago, while now, on account of heavy wage advances, the production cost is higher and, in some quarters, it was considered strange that the mills should not advance the price first and then let the orders come when they would. Now, however, all the indications are that in the not distant future the mills will need orders. For about six months, and until a fortnight or so ago, the mills were straining every nerve to produce every ton of steel possible, fuel supply being the limiting factor. Then there was a sudden shift. Now, the chief point is to get cars in which to ship the product. In general, consumers want more steel than the mills are able to ship. When transportation improves, or when the advent of winter brings about a lower rate of consumption, orders will be in demand.

Shipment Problems Serious

The car shortage is quite serious and the mills are complaining loudly. Possibly some of them are fearful lest, if shipments are delayed, their customers will not find themselves in as great need of the steel a few weeks hence. While steel production is tending to increase, the mills are more anxious to see heavier shipments than heavier production. At some plants the accumulations are growing uncomfortable and production in some departments may have to be curtailed. The most conspicuous instance of accumulation is with the Carnegie Steel Company which has 100,000 tons of finished and semi-finished steel awaiting cars. All this, of course, was made on order. The American Sheet & Tin Plate Company, which gets almost all its sheet bars from the Carnegie and Illinois steel companies, is operating at about 10 per cent. lower rate than two or three weeks, ago, on account of not receiving enough steel. A considerable tonnage has been rolled for its account and not shipped. It is motor trucking sheet bars from Duquesne to its McKeesport and Monessen works. The company has an ample sufficiency of orders and indeed its sheet obligations could not be completed by the end of this quarter even with a 100 per cent. operation. Of course, it is out of the market on sheets and will not be in again until it opens books for the first quarter of the new year. This leaves the sheet market entirely in the hands of independents, who are getting 3.50c to 3.60c for black sheets, according to delivery, etc., with 1.00c differential for galvanized sheets.

Bars and shapes are quotable at 2.00c to 2.25c and plates at 2.15c to 2.50c in the open market, according to tonnage, delivery, etc. The Steel Corporation price is understood to be 2.00c on all three products, but there is now very little buying for such deliveries as the corporation can make since it has a very large order book. In September its bookings were quite heavy in these lines, while a part of the rail business recently closed went on books in the month, and the pipe subsidiary booked an order for 100,000 tons of line pipe from Sinclair. Thus the unfilled tonnage statement is certain to show a large increase for September.

Production Recovers

Curtailment in steel production due to the coal strike reached its limit at the end of August, when the steel industry was operating at only 50 per cent. of capacity. The decrease was so sudden and the recovery has been so quick, operations being now about 70 per cent., that the loss in tonnage was small. It seems quite certain that production has not fallen below what would have occurred if the June rate had been maintained by as much as a fortnight. In other words, more steel will have been made by October 15 than would have been made by October 1 if there had been no decrease. From January 1 to June 30 the rate of steel production had been increasing continuously, except for a little backset in the first two or three weeks of April.

Production of steel ingots now may be guessed at about 36,000,000 tons a year, which is 20 per cent. more than production in 1912 and 1913, the two biggest years before the war, while exports are smaller. There is hardly the appearance of the country actually consuming steel at the proportionately greater rate. One does not need to be of a critical or pessimistic disposition to doubt whether the steel market rests upon a substan-

tial foundation to-day. If bumper crops—the most practical argument—are mentioned, the circumstance may be cited that some agricultural implement factories are working only four days a week, and then chiefly on stocks, not orders.

Prospects are that delivery premiums will have practically disappeared in a few weeks, leaving the market at basic prices, which are those of the Steel Corporation. Already there is speculation as to how far basic prices will decline in the next readjustment. They will not, of course, get down to the low point of early this year, for the double reason that costs are higher and that mills are unlikely to repeat the experiment of going to cost or below cost. It is not established that the performance did them any good. One prediction is that bars, shapes and plates will go to 1.75c. The mills will, of course, hold out for present prices as long as they can, and that may be many months.

While Connellsville coke production continues to increase, the offerings in the market are still very scant, relative to the possible demand. Many furnaces would like to blow in, but see no chance of picking up the requisite cost. Many more foundries are inquiring about coke prices than are actually buying. The market is a trifle stiffer than a week ago, furnace coke being strong at $12 to $12.50 and foundry coke strong at $13.50 to $14.

The pig iron market continues stagnant, with no clearly defined position. Very few valley furnaces have any iron to offer. Such prices as are quoted are too high for Pittsburgh delivery to meet the Cambria Steel Company, which is quoting $33 for Bessemer, $31 for basic, $32 for malleable and $32.50 for foundry, f.o.b. furnace. Freight from Johnstown to Pittsburgh is the same as from valleys to Pittsburgh, $1.77.

CANADA'S BUYING AND SELLING

Statistics show that in the matter of trade with the United States and United Kingdom, Canada buys $4 worth in the United States for every dollar spent in the U. K.; on the other hand, Canada sells more to the latter than to the States. Here are the figures:—

Imports	From U. K.	U.S.
Agric. & Veg. Prdtcs.....	25,435,111	79,122,891
Animal Products	3,177,463	34,943,067

An Infant Industry Building Helps Belleville's Expansion

CITIZENS of Belleville, in the early part of 1920, re-organized their board of trade and formed a chamber of commerce. Since then a great many difficult situations have arisen, many of which hampered the proper functioning of that body. The various units, however, have been working very smoothly for the last twelve or eighteen months, with the result that remarkable progress has been made, particularly from an industrial standpoint. The methods employed to accomplish these ends are rather unique, but since they have achieved success the theory behind them must be sound.

Such names as the Board of Trade and Chamber of Commerce suggest purely business organizations, but in Belleville the commercial side is only one of many lines of activity. The chamber first took an inventory of the assets of the city from the point of view of industrial expansion and at the same time looked into any drawbacks that were evident. From the point of view of shipping facilities the city has its advantages, as the three transcontinental lines pass through and there is an excellent harbor on the Bay of Quinte, which connects directly with Lake Ontario. The chamber then undertook to obtain factory sites. Simultaneously with these lines of activity other commodities were working along lines that were not generally accepted as falling in the spheres of activity of such an organization. These committees endeavored to make Belleville a city that would be attractive, all eyesores about the town were removed, citizens were encouraged to beautify their residences and places of business. Sporting activities were encouraged, social gatherings invited and a community spirit fostered.

The membership of the chamber was enlarged until nearly four hundred were enrolled. These included even the proprietors of the most humble business ventures, those young men destined to be the future business men.

A number of the most successful business men of the city organized the Belleville Industrial Corporation, Ltd., with a capital of $500,000.00, with the sole object of assisting in the development of the city and district. New industries are not encouraged to locate here and experiment with Belleville money, but in cases of worthy enterprises, already established and needing new capital for legitimate expansion, assistance is given. The industrial corporation takes existing structures and converts them into factory buildings, erects workmen's homes and purchases and holds available factory sites. The corporation purchased one large building and located a number of infant industries there. It was called an industrial incubator.

The city does not provide free sites does not give exemption from taxation, and does not offer cash bonuses or other unusual concessions. The policy of the chamber of commerce is to actively search out firms that contemplate locating in Canada. The advantages of the city are pointed out, and representatives are invited to inspect the city.

The result of this policy is that eleven new industries have chosen Belleville as their location in the last eighteen months. These firms are:—

National Castings Ltd., electric steel and iron castings; Natural Tread Shoes Ltd., footwear; Belleville Electric and Stamping, Ltd., electric appliances; American Optical Co., spectacles and optical goods; Bassick Alemite Corpn., Alemite lubrication systems, furniture, hardware, automobile accessories, etc.; International Burr Co., metal burrs; Asbestos Pulp Co., talc and talcum powder; Rubber Crepe Products Co., bathing shoes and rubber goods; Ashley Sweater Co., sweaters and knitted goods; Tiger Tire Co., tires, tubes and rubber goods; A. S. Richardson Co., display fixtures.

INDUSTRY REVEALS SIDELIGHTS

(Continued from page 21)

has had marked prosperity during the past few years. Serving the requirements of a limited market, the industry is in it infancy as compared with its status in the United States, yet it has given encouragement to many others, until to-day there are certain plants in which much expensive equipment has been installed and where enterprise has had elaborate scope. One of the most outstanding of these is the auto-stamping department of the Pedlar People in Oshawa. It was in 1915 that they became actively associated with the auto industry, by installing equipment to turn out stampings of sheet metal for bodies. It was natural that they should extend in this way, for they were manufacturing metal shingles, siding, ornamental ceilings and other similar products. It was predicted that it couldn't be done—at least not in Canada. But given the dies and the machinery and the engineering skill the proposition didn't seem to be impossible. Moreover there was a market to be retained in Oshawa where the McLaughlins were making cars. That the undertaking was successful is evident from the extent of that branch of the Pedlar plant to-day, where one wing of a new factory built two years ago, is occupied by auto-stamping machinery of all kinds. The floor space is 360 feet by 83 feet with a forty foot mezzanine. F. Reesor, the engineer, states that seven years ago a 2,000 run for one set of dies was considered a pretty fair record, while to-day a 25,000 or 30,000 run is a mere trifle. Such has the demand for motor cars grown. Here, too, is an instance of that industrial relativity which contributes so much to better business.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

Silicon, 2.25% to 2.75%	39 30
Algoma, No. 1, Montreal	41 65
Summerlee, Scotch, Montreal dock	35 00
Summerlee, Warehouse, 5-ton	40 50
Carron, Montreal docks	35 00
Grey forge Pittsburgh	34 27
Lake Superior, charcoal. Chicago	36 15
Standard low phos., Philadelphia	38 00
Bessemer, Pittsburgh	35 77
Basic, Valley furnace	33 50

News From the Industrial Field

Belleville Chamber of Commerce is putting on a "made-in-Belleville" exhibition, in the Armories, Oct 24 to 28.

James McEwan, an inspector with the John Bertram & Sons Co., Dundas, and who had been an employee of that concern since 1868, is dead.

Belleville.—Patterson Construction Co., this city, have purchased a ¾-yard steam shovel for use in the T. & N. O. Railway contract on which they are working at Fabre, P. Q.

Construction of the new technical school and collegiate institute in Guelph is going forward. It is expected that it will be ready for occupation with the second term of 1923.

William and Edwin Taylor have leased a foundry building in Galt, which they have equipped with wood planer, circular saw and buzz-planer, purchased from Preston Woodworking Machinery Co. They will operate under the name of Taylor Brothers in conjunction with building contractors.

Montreal.—In the year 1921 a total of 1,081 charters were granted new companies commencing operations in Canada, the whole representing a capitalization of $824,000,000. This year, during the first six months, new corporations have approximated $20,000,000 a week, and it would seem as if 1922 was going to create a record in this regard.

Montreal.—A despatch from London says that it is understood that a representative of the North Eastern Marine Engineering Company, Wallsend-on-Tyne, is about to go to Canada with a view to the establishment of a branch factory for the manufacture of marine engineering material in Eastern Canada.

Belleville, Ont.—Marsh Engineering Works have been able to dispose of a fair number of steam hoists, boilers, etc., this season. The firm has not been working to capacity but the sales are practically double what they were in 1921. Business is falling off, as it generally does at this season. Inquiries are coming in freely and prospects for next season are good.

Belleville, Ont.—Wm. Seward, president and manager of the Tiger Tire & Rubber Co., states that the sales of his firm were over half a million dollars for their year ending Sept. 30th. A chain of branches and dealers from Halifax to Vancouver has been completed. Since January 17th last till Sept. 30th a double shift has been employed. The night shift was only off one week when on Oct. 9th it was put on again to assist in overtaking orders. The factory may be enlarged.

Ottawa.—An influx of experienced agriculturists from Holland to Canada is likely, according to J. C. C. Sandberg, who is visiting Ottawa representing the government of Holland, which proposes a scheme of assisted emigration of farmers and agricultural laborers and their families. Sandberg is making a tour of Canada to investigate the possibility of settling the surplus of Dutch farmers.

Vancouver, B. C.—Based on returns from 532 firms, statistics concerning the lumber industry in British Columbia, show that the payroll for the past year amounted to $18,180,962. The average number of wage-earners was about 14,500. During May, June and July the number of men working was approximately 15,400, whereas during December, January and February not more than ten to twelve thousand men were employed.

Montreal.—Three world's records for unloading and loading grain have been broken at the port of Montreal during the last ten days. In one day 1,569,393 bushels of grain were loaded for sea, while 800,000 bushels were unloaded. This gives a total of 2 369,393 bushels moved in one day. Another world's record was broken for speed in unloading a vessel. A steamer arrived in port at 5.30 a. m., was berthed at 7 o'clock, delivery of grain was commenced at 8 o'clock and the vessel put out to sea the same evening with 242,000 bushels of grain in her hold.

Montreal.—Between thirty and forty thousand dollars are spent daily by United States tourists in Montreal, or approximately six million dollars for the six months period from May to October, according to the Secretary of the Automobile Club of Canada. For the province, he further states, the sum would be about $15,000,000, as Quebec and other points attract large numbers. In the principal hotels of Montreal, it is estimated 75 per cent. of the guests this last summer were from the United States.

Belleville, Ont.—Work on the new Coleman ward school is progressing satisfactorily. The local contractors, Thos. Manly and Son, expect to have the structure enclosed before the snow flies. The estimated cost of the building is $109,000. The school is to be equipped with an up-to-date heating and ventilating system. Four electric motors are being installed to drive the ventilating fans. A Keewatin boiler will furnish the steam. The building is of steel and brick construction, with steel sash and other materials that make it as nearly fireproof as possible.

Glace Bay, Nova Scotia.—With all its collieries working, the output of the Dominion Coal Company's mines is rapidly approaching normal. The average output of the mines is 14,000 tons a day, and officials of the company expect to reach this figure in a short time.

Ottawa.—About thirty-four per cent. of the automobiles now being used in India are made in Canada, according to a report from H. A Chisholm. Owing to the British preferential tariff Canada is rapidly becoming the centre for the export of motor vehicles, and each year sees new companies from the United States establishing plants in Canada to take care of their export business.

Edmonton.—Coal production in the Drumheller fields has amounted to 6,825 tons daily and will shortly be increased to between 8,000 and 9,000 tons. All the coal camps in Alberta and Eastern British Columbia are now working, and much of the product is being shipped to Saskatchewan and Manitoba. It is expected ample coal will be mined to meet all the requirements of Western Canada. The longest distance that Alberta coal has been shipped was recorded here when a local colliery forwarded a carload of egg coal to Levis, Que.

Toronto.—Gold production in Ontario for the first half of 1922 shows a marked increase over a similar period last year, and gives promise of an output exceeding $20,000,000 for the full year, as compared with $14,624,085 in 1921, according to returns received by the Ontario Department of Mines. Silver production also shows a corresponding increase over the corresponding period in 1920. The northern camps are becoming an important market for mining machinery and other heavy mill equipment.

Ottawa.—The preliminary estimate of the Bureau of Statistics of the total wheat yield of Canada for 1922 is 388,733,000 including fall and spring wheat, from 22,630,900 acres, or 17.25 bushels per acre, as against the 1921 estimate of 300,858,100 bushels from 23,261,224 acres, or 13.10 bushels per acre. Other grain yields for the whole of Canada, with last year's figures in brackets, are as follows: oats 558,358,000 (426,232 900) barley 76,395.500 (59,709,100); rye 49,601,800 (21,455,260); flaxseed 5,296,000 (4,111,800). The figures for 1922 represent the following forecast of total yields in bushels or tons: peas 2.945.000; beans 976 000; buckwheat 7,825,000; mixed grain 30,255.000; corn for husking 14,909.000; potatoes 102,686,000; turnips, etc., 80,796,000; fodder corn 5,635,000 tons; sugar beets 246 000 tons.

It's the Service that Counts
We carry the largest stock in Canada of new and re-manufactured machinery and supplies. This, combined with our long experience and our intimate connections with manufacturers in Canada, United States and Great Britain, enables us to offer you a service that is unique. No matter what you need in machinery, we either have it or will get it for you quickly at an advantageous price.
Our regular monthly machinery list is full of bargains? Shall we put you on our mailing list?
The A. R. Williams Machinery Co. Ltd.

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER
If its Machinery-Write "Williams"

Railway shopmen at Montreal have re-opened their wage issue with Canadian roads.

Acheson Graphite Co., Niagara Falls, Ont., are increasing the capacity of their plant to take care of enlarged export business. They are now replacing a 700 K. W. tranformer with one of 2,000 K. W. capacity.

Ford Motor Co., of Canada had net earnings of over five millions last year, equal to 71½ per cent. on the seven millions of stock outstanding. The company produced 45,000 cars and 1,192 tractors in the year which compares with 46.832 cars and 3.062 tractors in the preceding year. Receipts from sales were $8,563,219 below 1921, due largely to lower selling prices.

Belleville.—A. W. Robertson Co., have purchased the interests of the Quinlan Robertson Co., Montreal, in Huntington Township, fifteen miles north of Belleville, consisting of several hundred acres of pure lacustrine gravel. A railway siding is being built to the hill and workmen's cottages built. A dam is being thrown across a nearby stream from which it is proposed to develop power. Gravel handling appliances are being installed.

Guelph has a notable instance of family concentration in industry. The Callander foundry is operated by Alex. Callander, and his five sons, Malcolm, David, H. D., W. L., J. S., and E. J. Siefred. They report that business has been fairly good during the past Summer, particularly on good work for the building industry

Belleville, Ont.—F. B. Foley, manager of the Fruit Machinery Co., states that his firm has had a particularly successful season in their regular line of fruit and canning machinery. The contract work offering has been small and not of an attractive nature. The company expects to declare its regular dividend of ten per cent.

Quebec, Que.—There has been considerable activity in the pulp and paper industry in Canada lately. Michigan interests are negotiating with Kingston, Ont., with the view of building there a pulp and paper mill. The Premier Paper and Power Co., of Hartville, N. S., is about to instal a standard newsprint machine with a capacity of 15,000 tons a year. The average daily production of the Abitibi Power and Paper Co.'s plant during August was 462 tons, and on the 29th of the month it reached as high as 494 tons. The groundwood pulp mill of the Backus Brooks Company, near Kenora, Ont., is also well under way. Work has started on the new 13,000,000 plant of the Wigwam Pulp and Paper Company, at Elko, British Columbia.

Belleville Hardware and Lock Mfg. Co. state that the past season has been the best one in building trades for several years. Most jobbers allowed their stocks to get very low, and early in the year buying commenced. It has continued right up to the present time. Indications at this time are that 1923 will see even better records. Jobbers already are arranging for stocks to meet business expected to develop early in 1923.

Belleville.—F. A. Daniels, manager of the foundry of the National Castings Ltd., states that their new Moore rapid electromelt electric furnace of 500 pounds capacity, made by the Pittsburg Electric Furnace Co., has been delayed in transit, and it will be about two weeks before same is installed. This furnace will melt 1,400 pounds at one heat and can take off a heat every seventy-five minutes after it has been warmed up.

That Scotch and English pig iron, during the recent coal and rail strikes, was shipped into Western Ontario from Montreal at advantageous rates, is evident from quotations received by many of the foundries. One Guelph concern reports a price of $36.50, Guelph, for English pig, while another plant had an offer of Scotch pig iron at $37.75. This was the Guelph figure quoted by a Montreal firm at a time when the nominal Toronto price on domestic pig iron was $37.75.

Calgary Riverside Iron Works will establish branch works at Blairmore, Alta.

Vancouver, B. C.—Seaman Paper Mill Company of Chicago is planning to erect a large pulp and paper plant here. Power will be secured from Bridge River.

Bell Telephone Co.'s new East End exchange in Toronto will cost $175,000. P. H. Secord & Son Construction Co., Brantford, have the contract, which calls for completion in five months.

Fort William.—The new paper mill under construction at the Mission is ready for installation of machinery. It is expected that the plant will be ready for manufacturing by the first of the new year.

Waterville, N. S.—A pre-cooling plant of unique design is being installed in connection with the fruit storage warehouse by the Department of Agriculture. It consists of an ice tank with capacity of three tons, air ducts, gasoline engine and large insulated fan with capacity of 4,000 feet per minute. Air is forced through the ice tank in such a way as to ensure continuous circulation and even temperature.

Kingston.—With the opening of the locomotive works, there is ground for hope that orders for new locomotives are not improbable. It is pointed out that the Canadian railways are much in the position of the American railways—that is, that they have not been buying locomotives for some years and that they must therefore be in greater need of the new motive power than ever. Striking evidence of this, on the American side, is found in the announcement that the Baldwin Locomotive Co. has just secured some new large orders while the American Locomotive Co. has now orders on hand to the total value of $50,000,000. Hence the confident feeling that the "lightning will strike" in Canada also and that the railway companies will soon put in substantial orders for new locomotives.

Belleville.—Local officials of the Grand Trunk yard announce that some interesting tests have recently been made near Brockville. What is believed to be the heaviest train ever hauled over the grade just east of Brockville was taken out on Oct. 4th. The tests were made by the dynamo meter car of the eastern lines. The Mikado type locomotive No. 579 hauled 78 cars, 75 of them loaded with grain and heavy freight, over this grade, the total load being 5,054 tons. A further test was made on the 5th inst. when locomotive No. 685 of the superheated type, hauled 57 loaded cars and three empties over this grade, the total load aggregating 3,998 tons. These tests being conducted by the dynamo meter car are considered most satisfactory. The tests are for the purpose of ascertaining the draw-bar pull and at the same time registering the speed at which the train is travelling. Longer trains have been hauled over the grade but in the opinion of railroad men none of greater tonnage.

SIR HENRY THORNTON NEW HEAD OF C. N. R.

Major-General Sir Henry W. Thornton, K. B. E., is to head Canada's National Railway Board. For eight years he has been general manager of the Great Eastern Railway of England. He is a naturalized Britisher and a native of the United States. His salary is to be $50,000 a year. There is no doubt that a successful executive for the post will be worth such a salary.

SIR HENRY WORTH THORNTON
New Head of Canadian National Railways.

As to the board named to assist him, one hope will immediately stand out, and that is that the board was picked for something else than satisfying all parts of the country geographically. Two vice-presidents are to be picked from the present operatives of the roads and W. D. Robb and Mr. Hungerford are likely to be the ones chosen by the board.

Richard P. Gough, vice-president of the Sellers-Gough Company, furriers, Toronto.

Ernest R. Decary, notary and ex-president of the Montreal Civic Commission.

James Stewart, Winnipeg, prominent grain dealer, and ex-chairman of the Canada Wheat Board of 1919.

John H. Sinclair, K. C., of New Glasgow, N. S., who sat in the House of Commons for a number of years as Liberal member, first for Guysboro and subsequently for Antigonish and Guysboro, N. S.

Frederick G. Dawson, of Prince Rupert, B. C., wholesale grocer.

Tom Moore, president of the Trades and Labor Congress of Canada, as representative of labor.

Graham A. Bell, Deputy Minister of Railways and Canals, representing the Dominion Government, and

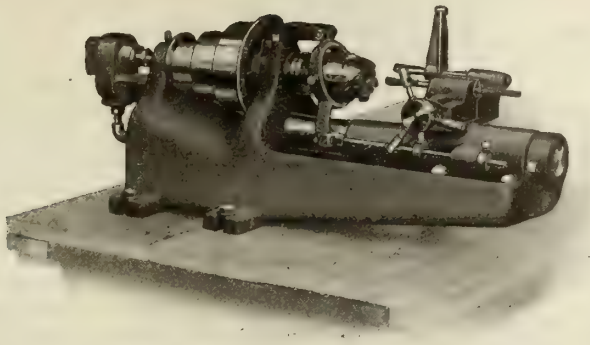
Gerard G. Ruel, who has been general counsel of the Canadian Northern Railway and is to be general counsel for the whole Canadian National System.

MARKET FOR CANADIAN EDGE TOOLS

That Canadian manufacturers of edge tools able to meet competition in the Dominion ought to be able to establish a trade in Argentine Republic is the report of B. S. Webb, trade commissioner. He states that this is proved by the fact that Canadian made picks, forks, hammers, shovels, and axes have been sold there, some of them without interruption, for the past ten years. One Canadian factory has sold edge tools there, year in year out, to the value of $50,000 per annum, the line comprising hammers, axes, picks, and rolled forks. That the trade will be finally profitable is reasonably sure, but it cannot be expected to prove lucrative at the commencement. A glance at the list of foreign manufacturers whose local representatives are and have been for many years actively canvassing the trade will be sufficient to suggest that the competition to be met is decidedly keen, and a feature of the market which must constantly be borne in mind is the fact that consumers there attach exceptional importance to the question of a trade mark, making it a long and uphill task to place an unknown make of tools on the market in the face of the competition to be met from the manufacturers whose trade marks are already well known amongst consumers. Importers as a class are not at all interested in pushing an unknown mark as, rightly or wrongly, they consider their mission is to supply the trade with the goods it asks for. The importer himself may admit that a certain article is of superior quality and cheaper than another for which a demand exists, but will still maintain the attitude that it is easier to give the customer what he asks for than to educate him up to the recognition of the merits of an unknown article. On the other hand, once a make of tools is well placed on the market, steady trade will result, but from the foregoing it is quite clear that tools cannot be sold there in a desultory manner: the manufacturer makes exceptional efforts to get his goods on the market and he either definitely succeeds or definitely fails, there being no half measure. Quotations should always be in Canadian money.

Comparison of the trade of Australia with that of Canada during the past two fiscal years shows that in 1920-21, Canada's trade was $2,450,587,001; Australia's, $1,434 945,282. In 1921-22, Canada's trade was $1,501,731 341; Australia's, $1,113,003,743—a very material falling off in the past year.

With the exception of his eyes, a workman's hands are his most valuable possessions. Stopping a machine before cleaning it, and using a brush or stick for removing accumulated waste material, will greatly help to reduce the number of accidents to hands and fingers.



Geometric Bench Threading Machine

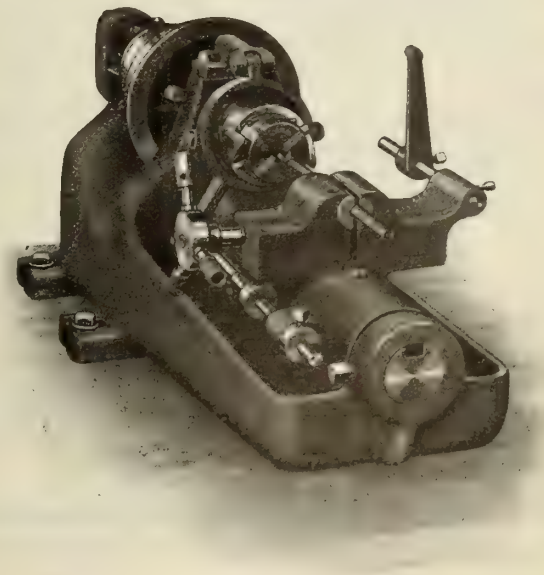
Compact
Sturdy
Complete

Right in the Lead

ANOTHER GEOMETRIC LEADER

Brings Down Production Costs

The Geometric Bench Threading Machine is a wonder on small threaded work. It weighs but 90 pounds and takes bench space of only 9½″ x 29 inches. The 5-16″ Geometric Rotary Die Head with which the machine is fitted cuts threads of standard and finer pitch on diameters of 1-16″ to 5-16″ inclusive. The machine is arranged for bolting to a bench, or it may be mounted on a separate pedestal for floor use.



Send for the Circular.

Canada Saw Co.
LIMITED
"The Saw Makers"
MONTREAL - QUEBEC

St. John, N.B. Vancouver, B.C.

Dent's-Griffiths, makers of fine silk gloves, have started operations with 50 hands in their new plant, St. Catharines.

In the Made-in-Belleville exhibition which will be opened by the Lieutenant-Governor, Oct. 24, some seventy firms will be represented. Those engaged in iron and steel or allied industries are: National Castings, castings and metal goods; Belleville Electric and Stampings, electric appliances; Steel Company of Canada, horseshoes and iron and steel products; Marsh Engineering Works, hoists, boilers and special machinery; Weed Harvester Co., harvesting machinery; Belleville Sash and Door Co., wood products; Brown, Sword & Co., wood products; American Optical Co., spectacles and optical goods; Bassick Optical Co., Alenite lubrication system, furniture, hardware and auto accessories; International Burr Co., metal burrs; Asbestos Pulp Co., talc and talcum powder; Belleville Hardware and Lock Co., locks and builders' hardware; Canada Cement Co., cement and cement products; Elliott Woodworking Machine Co., woodworking machines, electric washers, school desks; The Greenleaf Co., castings, ironware and other products; Quinte Battery Service Co., storage batteries and ignition systems; Consolidated Distilleries, industrial alcohol and other products; G. T. R. shops, locomotive models, drawings and parts of engines; Springer Lock Mfg. Co., locks and builders' hardware; Tiger Tire Co., tires, tubes and rubber goods.

One of the most common as well as serious evils of lighting installations is glare. Any brightness, whether from a light-source or from reflected light within the field of vision, and of such a character as to cause annoyance, discomfort, interference with vision, or eye fatigue, is glare.

"Maple Leaf"
BRAND
Stitched Cotton Duck Belting

More Power
At Less Cost

This is possible if you use ONLY "Maple Leaf" stitched cotton duck belting. It has a positive gripping surface which hugs the pulley. Costs less than leather, rubber or balata.
Once you use "Maple Leaf" belting you specify it always for it is the NO TROUBLE belting which helps production. Write us for samples.

Dominion Belting Co. Ltd.
Hamilton, Canada
Quebec Branch: 51 Duluth Bldg., Montreal

GENERAL BUSINESS IMPROVES SLOWLY

"That business is on the up-grade," seems to be the general consensus of opinion among leading manufacturers in Galt. A few firms report no improvement during the last two months, but these are in the minority, and are making lines which cannot help but be slow to pick up. For example, L. W. Smith, manager of the Greenfield Tap & Die Corporation, told Canadian Machinery that business is much improved in their lines, and that on one particular article alone, they are about two months behind on delivery. Enquiries are better, and from present outlook, October should show quite a bit of improvement over September. As last month was ahead of August, the improvement seems to be sure and steady.

Mr. Jansen, of the Galt Machine Screw Company, also states that September was a better month for them than August. He describes the improvement as slight but steady, and says that the demand is of a general nature, no one line being affected more than another.

Mr. Elliott, of Elliott and Whitehall, says that the small orders are better, but on large work, conditions are still somewhat quiet. He expects, however, that October will show a decided improvement over September. When commenting upon enquiries he mentioned that the best way to get business was not to sit down and wait for enquiries, but to go out and hustle for the orders.

J. H. Cowan, secretary-treasurer of the Cowan Co., and W. L. Cowan, plant superintendent of the same firm, told Canadian Machinery that following the Toronto Exhibition, business picked up slightly, and has been improving slowly but steadily since then. Both these gentlemen do not look for any sensational improvement, but hope that the present upward trend will continue.

A HUNDRED-INCH SLIDE RULE

Every engineer is reputed to carry a slide rule and to use it a hundred times a day for every conceivable kind of calculation. The ordinary pocket slide rule is, however, not accurate except within rather wide limits; and when a finer margin of error is desired it is necessary to employ a rule of larger dimensions. A British firm has recently brought out a slide rule in which the scale is 100in. long and can therefore be relied upon to yield results in multiplication and division with an error of less than one in one thousand. The scale is arranged in twenty parallel lines, each about five inches long; and the whole thing is arranged so that the rule can be operated with one hand while the other holds the pen for recording results.

A Directory of Dealers will be Found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

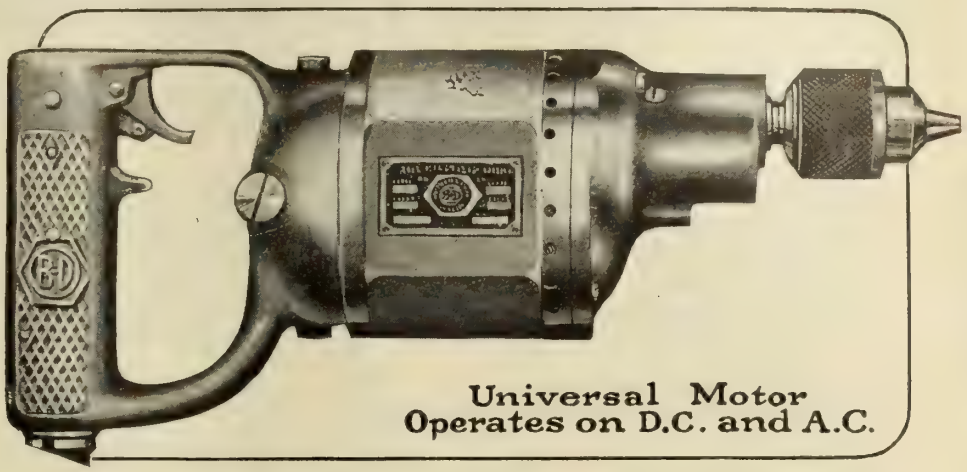
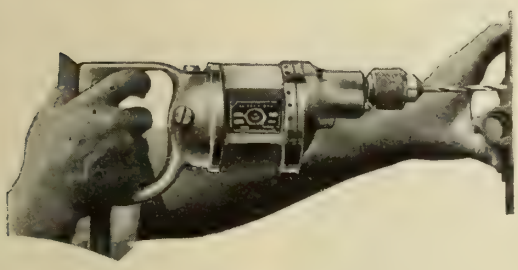
1922 Price



Universal Motor
Operates on D.C. and A.C.



Standard Black and Decker Portable Electric Drill, *"With the Pistol Grip and Trigger Switch."*

In design and construction the same as the larger sizes. Powerful, durable, comfortable to handle and perfectly controlled. Nothing in the way of ability or durability has been sacrificed to obtain this light weight. Particularly adapted for close corner drilling.

Very accessible. All bearings removable and renewable. By removing four screws, complete switch mechanism, motor commutator, field leads and cable terminals may be uncovered. Armature bearing is carried in a spider integral with motor case, consequently drill may be inspected or commutator cleaned while machine is running.

Brushes may be quickly and easily renewed from outside of motor case. Flexible cable is attached to screw terminals on the switch block so that cable may be renewed when necessary quickly and easily without soldering any joints.

SPECIFICATIONS

HOUSING—Aluminum alloy (No sheet metal is used)

MOTOR—Constructed and insulated the same as the larger Black & Decker Drills. Universal. Operates on direct or alternating current.

AIR COOLED—

GEARING—Double reduction stub tooth gears, cut from chrome nickel steel, heat treated (The toughest, longest wearing gears engineers have been able to design.)

NOTE—No brass gears are used in any Black & Decker tools.

CONTROL—*"The Pistol Grip and Trigger Switch."*

CHUCK—Three jaw chuck for straight shank drill bits up to ¼ inch.

FLEXIBLE CORD—Special light weight rubber covered duplex electric cable, fitted with separable attachment plug.

NO LOAD SPEED—1600 R. P. M.

NET WEIGHT—5 pounds.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

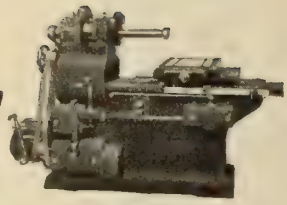
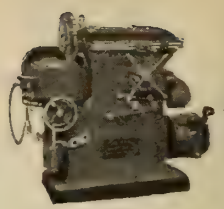
GRIND WITH A

HEALD

AND BE SURE



Cylinder Grinder



Surface Grinder

A Machine for every Internal and Surface Grinding Requirement

Machines especially designed and adaptable to one particular class of grinding work are greatly in demand to-day. The efficient manager recognizes the folly of purchasing anything that is not exactly suited for the job.

For instance, on large, short work without question a simple hand feed machine is far more productive and less expensive to buy and maintain than a valuable automatic. While, on the other hand, long work and where the utmost precision is demanded it is absolutely necessary to use a machine with an automatic feed for the table.

The same holds true regarding small work. It is possible to put small wheel heads on a large machine and do the job satisfactorily, but why tie up a large investment when a similar equipment of small size is better, more economical, easier to handle and takes up less room?

The success of the Heald Company in the grinding field is largely due to the fact that they have a complete line of internal and surface grinders which enables them to handle each and every condition to the best advantage of their customers.

Possibly you have work on which there is a bit of doubt in regard to the method of holding, production time, wheel speed, proper machine, etc. If so, send us samples or prints and our Engineering Service Department will give you full data.

Let's get together on that grinding job to-day

The Extensive Heald Line Covers Your Needs

Style No. 80. Automatic Internal Grinding Machine for small, long work.

Style No. 85. Hand Feed Internal Grinding Machine for small, short work.

Style No. 70. Automatic Internal Grinding Machine for medium work, both length and size.

Style No. 75. Hand Feed Internal Grinding Machine for medium sized short work.

Style No. 50. Cylinder Grinding Machine for a great variety of large, awkward-shaped work.

Style No. 20. Surface Grinding Machine for single work. Has 8 in. capacity.

Style No. 22. Surface Grinding Machine for large single or multiple work. Has 12 in. diameter capacity.

Style No. 25. Surface Grinding Machine. Has automatic feed for chucking work. Ideal for piston rings, collars, ball races, etc.

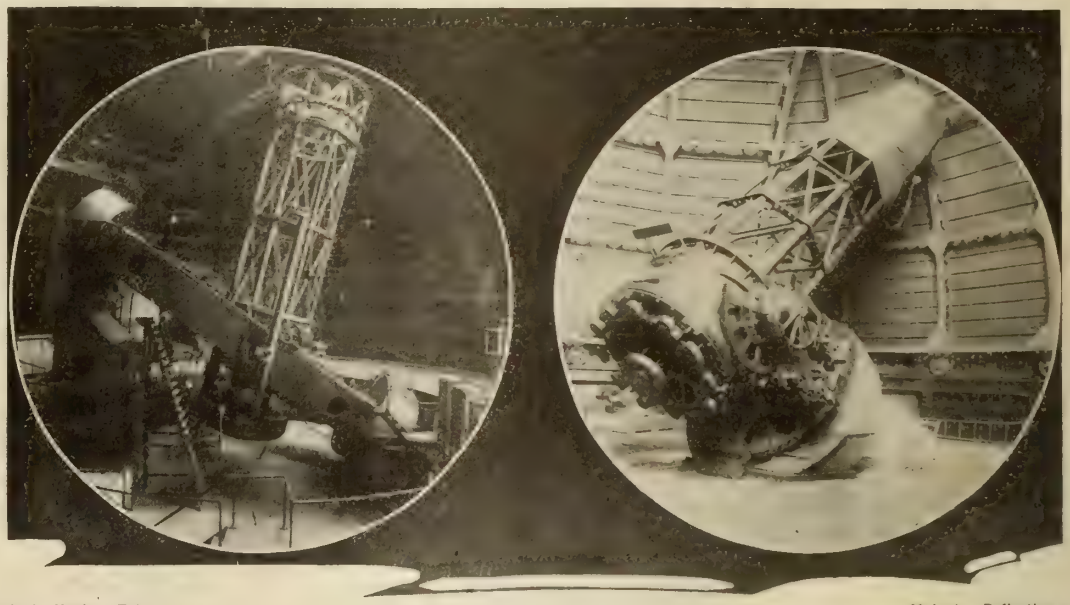
SKF



100-inch Hooker Telescope with Cassegrain spectrograph.

60-inch Reflecting Telescope from the west.

The World's Largest Telescope

—*Weight 650 Tons*—Ball Bearing Equipped

Only 50 H.P.—divided between 40 small motors—is required to operate the great 100-inch telescope of the Mount Wilson Observatory—the largest in the world.

The massive 550-ton dome, mounted on 23 ball-bearing equipped trucks, responds to the traction of two small 7½ H.P. motors. Altogether, over 200 **SKF** marked ball-bearings support the dome and the telescope's 100 tons of moving parts.

The companion of this powerful instrument, a 60-inch telescope — likewise at Mount Wilson — is also equipped with **SKF** marked ball bearings.

The fact that ball bearings are very accurate, practically frictionless and show no appreciable wear, contributes much towards maintaining the delica e movement and ease of adjustment so essential where millions of miles are measured by a mere fraction of an inch.

What ball bearings accomplish under these extraordinary conditions is a good indication of their value in the commoner machines of industry and science.

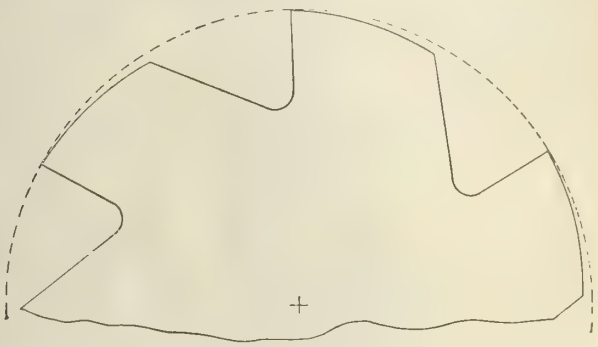
PRATT & WHITNEY

Reamers

With Eccentric Relief

THE cut below shows our patent eccentric relief which is an exclusive Pratt & Whitney feature. Eccentrically relieved Reamers, as made by us, have the distinguishing advantage that they can be sharpened by grinding on the face of each flute, thus retaining a true working size for a much longer period than is otherwise possible.

Pratt & Whitney Reamers are the only reamers having this eccentric relief, which should not be confused with the so-called "Eccentric tooth," which is nothing more than unequal spacing and adds nothing to the life of the tool.



--a stronger tooth--a smoother hole
--no chatter--maintained size

All P. & W. Adjustable Reamers have **eccentric** relief, can be set to size without regrinding and can be made to **face the bottom of a hole.**

In order to set these reamers, it is only necessary to loosen the shoes and run back the nuts. The blades can then be pushed back and the shoes tightened slightly. Then, upon coming up with the adjusting nut, the diameter will gradually decrease until the desired size is obtained. Lock-nut and shoes are now firmly tightened and the reamer is ready for use. Quick, positive and convenient.

Be Sure They Are Stamped Pratt & Whitney

These reamers are made with 12 different sizes of bodies, giving an adjustment from .020 to .060 in., according to the diameter. Shell, hand or chucking reamers with the same number of body have interchangeable nuts, shoes, screws and wrenches. Shell and chucking reamers with the same number of body have interchangeable blades also.

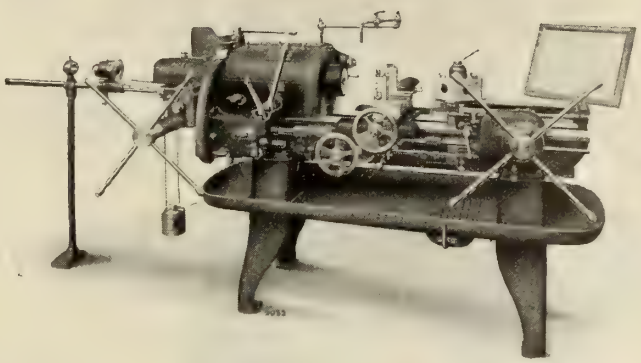
ECONOMICAL on the Small Quantities Too



THE No. 4 Herbert Capstan or Universal Turret Lathe illustrated presents a rapid production, exceedingly versatile machine. It will handle bar work in the draw in chuck up to 1⅝″ x 10″ long. The swing is 13″ over the bed. The cross saddle is provided with a positive leader chasing mechanism. The range of standard tools available from Toronto stock enables an exceedingly large percentage of brass and steel work to be done without special toolmaking.

The words turret lathe and quantity with many are synonymous. This is a mistake. Quantity is a relative term. On some work six is a quantity which will pay handsomely. We would appreciate an opportunity of investigating your work and reporting to you fully as to the possibilities of savings by the introduction of turret lathes.

A Finish Fight

This Advertisement is one of a series based on actual occurrences

THE smaller crab, more aggressive, had all the best of the battle. The larger one was handicapped because he had only one fighting claw.

How strikingly this battle sums up the story of a recent experience of our own in a large machine shop. It was a question of which should survive, old methods —or new.

The job was to remove machine oil from brass tubes before japanning. The old method of cleaning with caustic was slow and gave frequent trouble.

Resident Canadian Representatives:
Mr. C. Burgin, Montreal,
Mr. C. P. Murphy, Toronto

New methods were instituted and Oakite Platers' Cleaner went at the work aggressively, like the young crab, and took hold with all its claws. It cleaned the work perfectly, ***3 times faster*** than caustic. The tubes were made absolutely clean before japanning, a condition never before possible when caustic was used. A considerable saving in money resulted from the elimination of rejects—and naturally O.P.C. won the battle.

Wouldn't you like to clean your work ***3 times faster*** and cut out rejects in your shop? Let us stage a competitive test in your plant between Oakite materials and whatever you are using. Under our liberal guarantee we will ship you enough Oakite materials for a 30-day trial. If we can't clean your work faster, better and for less money, it won't cost you a cent.

That's fair, isn't it? May we ask one of our experienced Service Men to call to arrange the details with you? Write us.

For Making Perfect Screw-Thread Joints

SMOOTH-ON
ELASTIC CEMENT NO. 3

A screw-thread joint made with Smooth-On Elastic Cement No. 3, will not leak, because the Smooth-On expands in metallizing and so closes up any defective places which otherwise would cause leaks; yet, the joint may be taken apart when desired.

Smooth-On Elastic Cement, No. 3, is sold ready for use in paste form. It is applied to the screw-threads with a brush. Especially useful for high pressure steam or water joints, for ammonia joints, for coating flanged joint faces and for coating gaskets.

Send for our NEW Smooth-On Instruction Book No. 19. It illustrates and describes how to make perfect screw-thread joints and hundreds of other repairs. You will marvel at its contents. The book is **FREE.**

Smooth-On Elastic Cement No. 3 comes in 5 lb., 10 lb., and 25 lb. tins. Also in larger sizes.

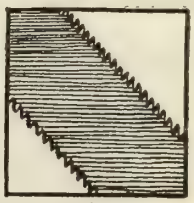
No, thanks— I've sworn off on 'freaks'—

"I used to be easy meat for freaks and 'all-around, general purpose' things. Got so I'd try *anything*, as long as it was different. Trick spoons and plugs that were guaranteed to do everything short of causing the fish to jump into the boat. I had 'em by the score but the fish they hooked could be counted on my fingers.

"Funny shaped putters that were supposed to remove the human element on the green—actually I got to experimenting so much that my game was all but ruined before I came back to earth and threw out the lot.

"And it was the same story with hack saws. I remember one we tried out that had two cutting edges—the theory was that it would last twice as long as the others. When we put it to work, however, the upper edge was so dulled by friction as it passed through the cut that it was impossible to make even *one* cut with the blade turned. Others were not quite so bad, but I'm through experimenting with 'freaks'! It's too expensive with labor and overhead so high.



"Look in my tool room today and you'll find Starrett blades only, in the hack saw section. They represent the very best experience in hack saw manufacture and I *know* they're reliable. And I'd have saved money if I had quit experimenting earlier."

Send for Catalog No. 22"3" and the Supplement showing the newest Starrett Tools

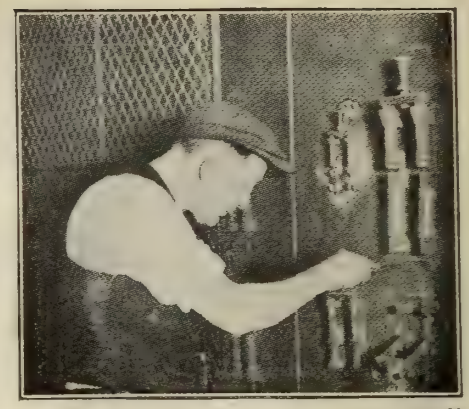
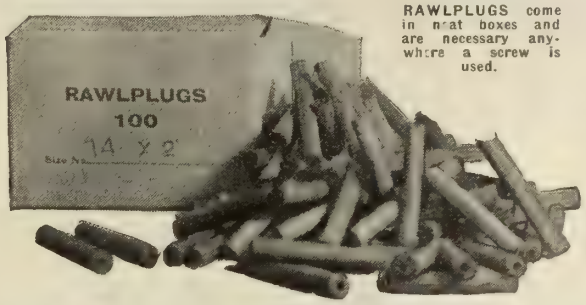
RAWLPLUGS

Hold Screws in any Material

The Greatest Idea in Years. Machine Shops, Builders, Contractors, Electricians and all other trades find RAWLPLUGS indispensable. No skilled handling required. Can be used in either hard or soft materials and will hold firmly under all conditions. They are low in cost and save time.



Can be placed in Brick or Cement Wall



RAWLPLUGS come in neat boxes and are necessary anywhere a screw is used.

A Special Alloy Steel Tool shown below makes the hole. Two tools, which are interchangeable in the one holder, are used. The first, "A," is used in Brick, Concrete, Metal, or any hard material, while the tool "B" is used in Plaster or any soft material. Find out how useful RAWLPLUGS are by ordering a box at once. We have a mechanic's outfit which comes complete and is very reasonable in cost. Let us tell you all particulars about it.

The $36 Workman on the $3700 Job *Makes Good*

How Clipper Belt Lacers Cut This Firm's Operating Costs

A well known manufacturer—name on request—reports that two $35 Clipper Belt Lacers save $3700 annually. One millwright using two Clippers spends three hours a day caring for more than 500 belts ranging in width from 1" to 6".

Formerly it required 20 minutes to repair a broken belt. Now ten minutes does the entire job with the Clipper. Idle man time and idle machine time were cut in half. In addition, the life of clipper joints averaged 40% longer than hand lacings because the Clipper neither cuts nor punches the belt.

Packard Motor Car Co., Dodge Brothers, Klaxon Company, International Silver Co., are a few of the thousands of companies using Clipper Belt Lacing.

To Jobbers and Dealers in Mill Supplies

The Clipper is a nationally advertised cost-cutting tool that every factory and shop needs. Rapid turnover of 3 sizes, one shown being largest. Steady sales of carded hooks at good profit. Ask for our proposition. (1)

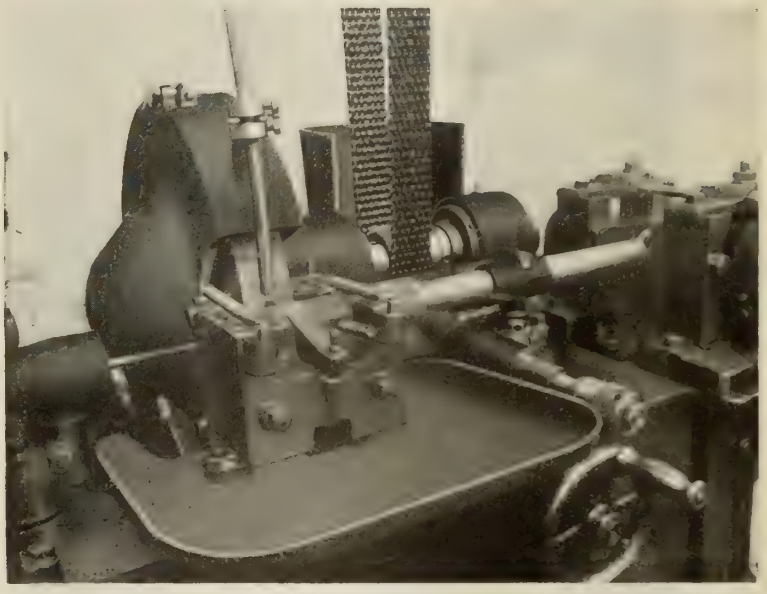
RENOLD CHAIN DRIVES



An Interesting Experiment

was made to obtain the comparative efficiencies of Belt and Chain driving on a number of Grinding Machines designed for the grinding of steel rods up to .375-in. diameter; 7 to 8 ft. long; to a working limit of .00025-in. The original spindle drives on these machines were by belt from three-speed countershafts. These belt drives gave considerable trouble due to slip, which resulted in irregularity in size and finish of the rods and considerable loss of time in keeping the belts sufficiently tight to stand up to the work. The life of the grinding wheels was uncertain, and time spent in trimming up kept the machines idle many hours per day.

Inverted Tooth Chain was fitted to the spindle, as shown above. Roller chains were also fitted in place of the round leather belt feed motion drives which had been giving trouble owing to slip, causing irregular feed which, in turn, necessitated a close watch on the rods for flats, finish and size.

The Result

of these conversions was an immediate improvement, there being a 40 per cent. increase in production during roughing, and a 20 per cent. increase during finishing. The number of passes on the rods was reduced accordingly and the net power saved was 26 per cent. In addition, the wheel consumption was reduced and the productive hours increased by less frequent trimming up of the grinding wheels.

Let us show you how "Renold" Chain Drives will benefit you.

MANUFACTURING NEWS

VOL. XXVIII, No. 16 OCTOBER 19, 1922

Automatic Production in a Locomotive Works

Blanks, Castings and Forgings Successfully Machined—Work Must be Carefully Checked—Special Jaws for Irregular Shaped Pieces—Multiple Tool Holding Fixtures—Overhead Pilot

THE auto lathe, or automatic turning machine as it is sometimes called, is in reality a turret lathe for dealing with detacned pieces such as blanks, castings and forgings on which all cutting operations proceed automatically after the work has been chucked. When the cycle is completed, the machine stops automatically: a new piece is put in the chuck by the operator and the machine re-started. It is possible, therefore, for one operator to attend several machines, so that the labour cost per machine hour is low. Where the quantities of work which can be put in hand at one time are sufficiently large to justify the use of auto lathes, this type of machine produces work at a lower cost than the combination turret lathe, although the machining times may be approximately the same.

At first sight, it might appear that in a locomotive works it would hardly be possible for the auto lathe to be a paying proposition, yet by careful standardization in the design of component parts of the locomotive, it is possible to put large batches through for stock and draw upon them as required.

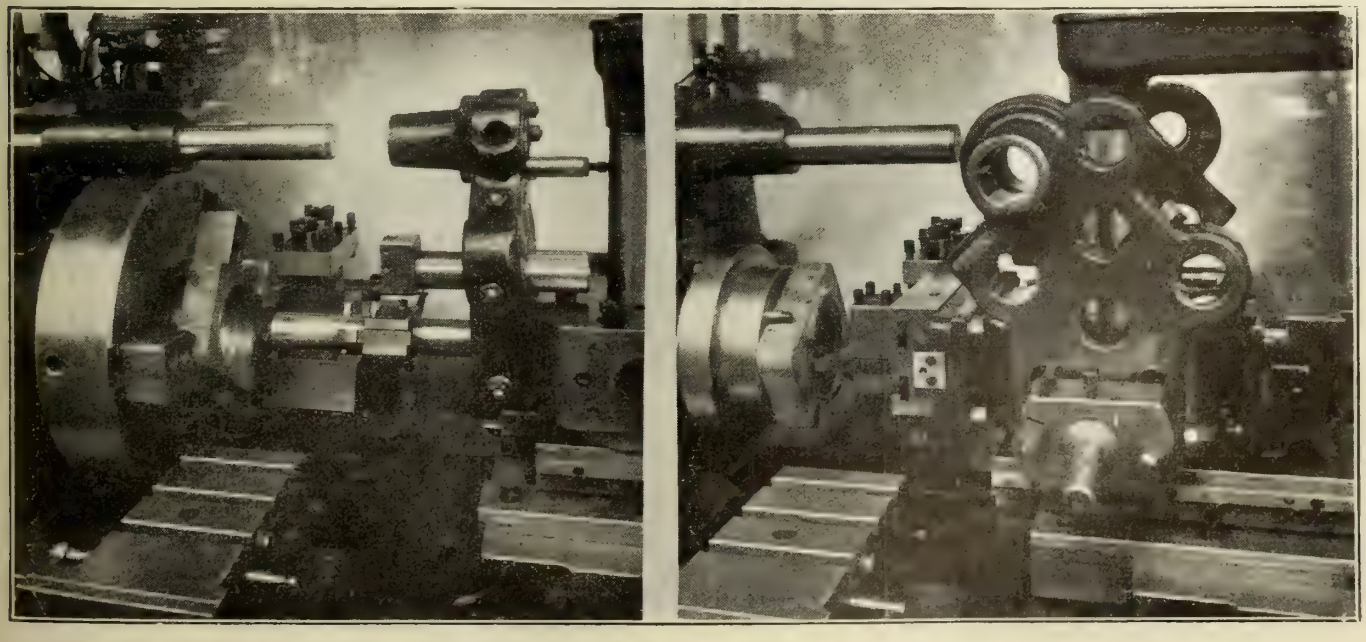
About the first railway company in England to consider the possibilities of auto lathes on locomotive work was the Lancashire & Yorkshire Railway Co., of Horwich who, in 1912, examined the question from their own point of view. After careful consideration of the estimated production times on various pieces of work which were considered suitable, three automatic turning machines were installed, two of the No. 4 size and one of the No. 2 size. The work for which these machines were ordered included the following parts:—wash-out cap nut, safety valve chuck, mud collector cover, coupling rod bush, reversing shaft bush, air pump, piston head, radial check spring bush, train pipe syphon, feed pipe flanges (round and oval), connecting rod nut, suspension stay bolt, spring link adjusting nut.

This method of production proved profitable and two more No. 4 "Herbert" machines were installed in 1913. During the war the continuation of this policy was temporarily suspended, but recently a larger machine, a No. 6 automatic turning machine, was installed. This machine was supplied with tool equipment for a number of parts which are typical of those which can be economically handled by automatic methods, and the purpose of the present article is to consider in detail the machining methods on these parts as illustrative of the possibilities of this type of machine on work of this class.

Piston Rod Gland

The piston rod glands are made from rectangular iron castings 7¾ inches x 6⅛ inches, the leading dimensions of which are given in the detailed view at the top of the layout for the first operation, Fig. 1. The chucking is particularly interesting as it shows the adaptability of the Coventry concentric chuck to irregular objects by the use of special jaws.

Illustrations and information through courtesy of Alfred Herbert Co., Coventry.



Figs. 2 and 4.—Set-up for first and second operation for machining piston rod gland.

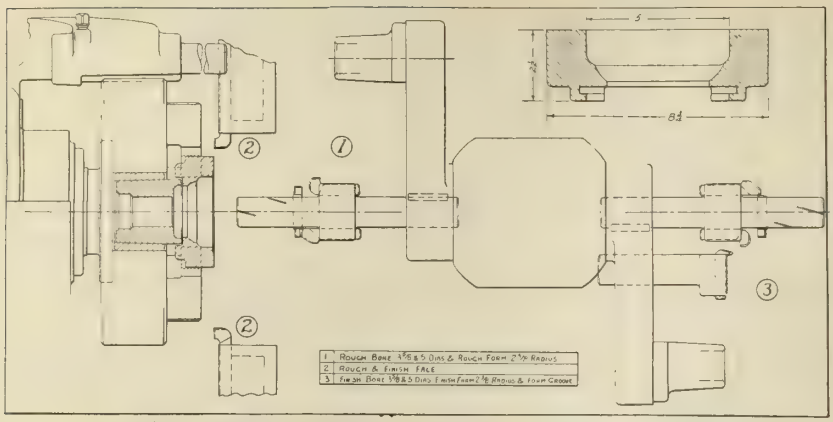


Fig. 1.—Tool layout for first operation on piston rod gland.

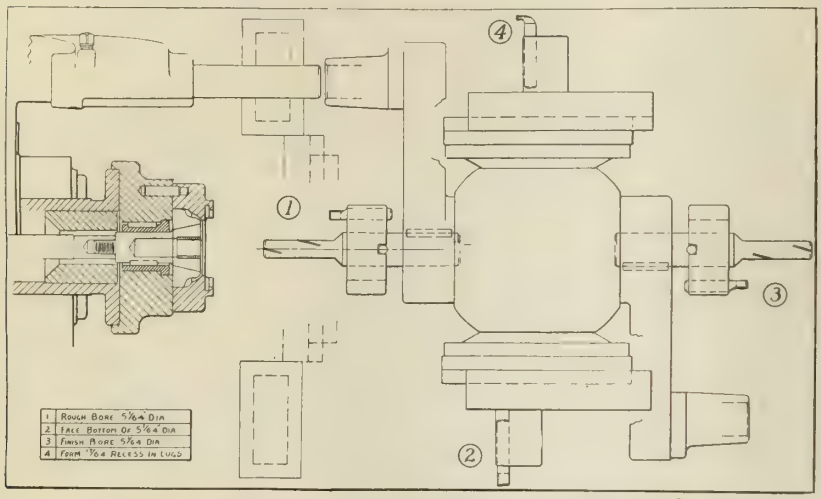

Fig. 3.—Tool layout for second operation on piston rod gland.

At first sight it might appear that the chucking of this casting was legitimate work for a four-jaw chuck, but with independent jaws chucking would obviously be a slower operation, and moreover the work might possibly get out of truth unless carefully chucked. With the Coventry concentric chuck, once the jaws are set it is easy to chuck this piece of work as an ordinary circular object.

In order to facilitate identification of the tools throughout the following descriptions, they have been numbered on the layouts for reference.

Tool No. 1 is a boring bar which carries a rounded cutter for roughing the small bore. An enlarged portion on this bar carries two form boring cutters for dealing with the two other portions of the bore. Simultaneously with this boring operation, the back and front cross slides come in for facing. A roughing tool is carried on the back and a finishing tool on the front tool post, the roughing tool being set to cut about ⅛ in. in advance of the finishing tool. From a production point of view it is a great advantage to have these two tools operating simultaneously, and it is an important feature of the Herbert design that this can be done with the independent cross slides which can be set to operate together or independently at any part of the cycle as desired.

Tool No. 3 is a boring bar with cutters similar to No. 1, for finishing the corresponding surfaces. It is clamped in a standard combination tool holder which also carries a turning head in which is fixed a small cutter for grooving the face of the gland. It will be noted that both boring bars are piloted in the chuck steady bush: it is good practice to make these steady bushes taper on the outside and fit them into a liner with a taper bore which is left in the chuck. The taper is approximately the same included angle as a Morse taper, and facilitates removing the steady bushes from the chuck. The set-up of the machine on the first operation is shown in Fig. 2.

At the second operation—Figs. 3 and 4, the work is chucked on an expanding drawback arbor bush operated by a handwheel at the rear of the spindle. The tapered peg is bored out and fitted with a phosphor bronze liner which serves to steady the boring bars used at this operation. A positive drive to the work is obtained by a pin fixed in the faceplate, engaging one of the sides on the casting.

Tool No. 1 is a bar carrying a cutter head for rough boring the counterbore. Tool No. 2 is a slide facing tool for machining the face at the bottom of this counterbore with a traversing cut. This is better practice than coming on to scale with a flat cutter, as scale would rapidly destroy the cutting edge. Instead, the slide facing tool is attached to the turret which is brought forward to the work and held stationary by means of a retaining cam, while one of the tool blocks carries a simple cutter. A piece of rectangular stock in the tool post, or the tool post itself, then comes up against the slide with the ordinary cross slide feed and pushes over the tool slide which thus machines the inside face with a traversing single point cut.

Tool No. 3 is a boring tool similar to No. 1 for finishing the counterbore. Tool No. 4 is another slide facing tool carrying a hooked cutter for forming the undercut. As in the case of No. 2 this slide is brought forward and held stationary while it is pushed over by the back tool post. The machining time for the two operations is 22 minutes.

Machining Valve Head

The valve heads are made from iron castings which at the first operation—Fig. 5, are gripped under the head by special jaws in the Coventry chuck. This is often a very helpful way of gripping the work as it frequently enables the whole of the outside to be machined at one chucking, thus avoiding the necessity of matching up. It is a very important point, therefore, in the choice of a chuck to see that it is equally power-

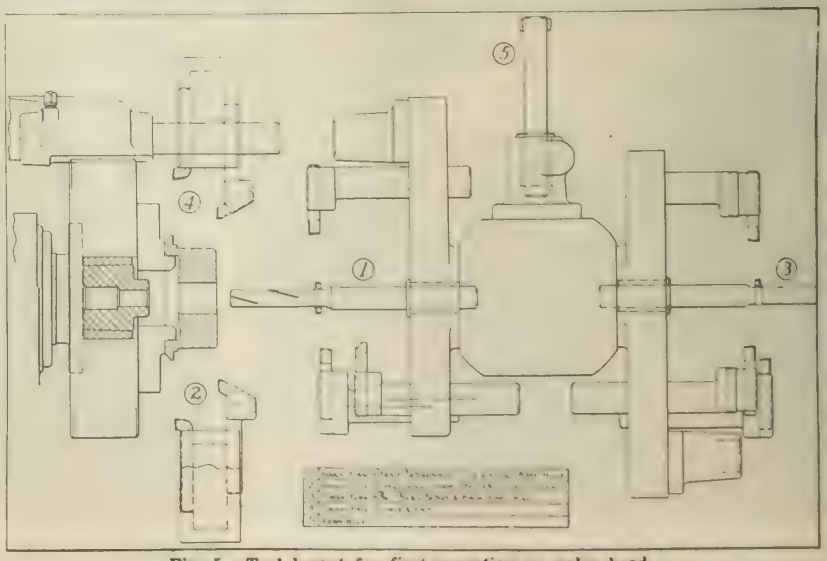

Fig. 5.—Tool layout for first operation on valve head.

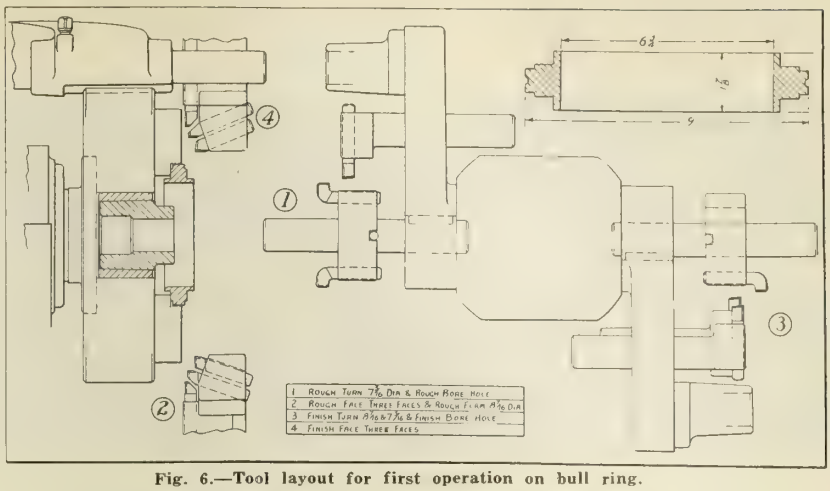
ful in gripping outwards as well as inwards.

Tool No. 1 is a combination tool holder carrying a boring bar with a double ended cutter for roughing the 2⅛ in. bore, two turning heads with cutters for the external diameters, and a radius form tool for the end. Simultaneously with this, the front cross slide operates, facing the large shoulder, forming the short diameter, and facing the end. The cutting tool for the latter surface is carried in a special holder which enables it to be ground straight from a piece of black square stock by the Lumsden method. It is often economical in cases such as this to make a special holder as the cutting tool is then a cheap replacement, whereas the cost of the holder never recurs.



1 Rough Turn 7/16 Dia & Rough Bore Hole
2 Rough Face Three Faces & Rough Turn A 7/16 Dia
3 Finish Turn A 6.6875 & Finish Bore Hole
4 Finish Face Three Faces

Fig. 6.—Tool layout for first operation on bull ring.

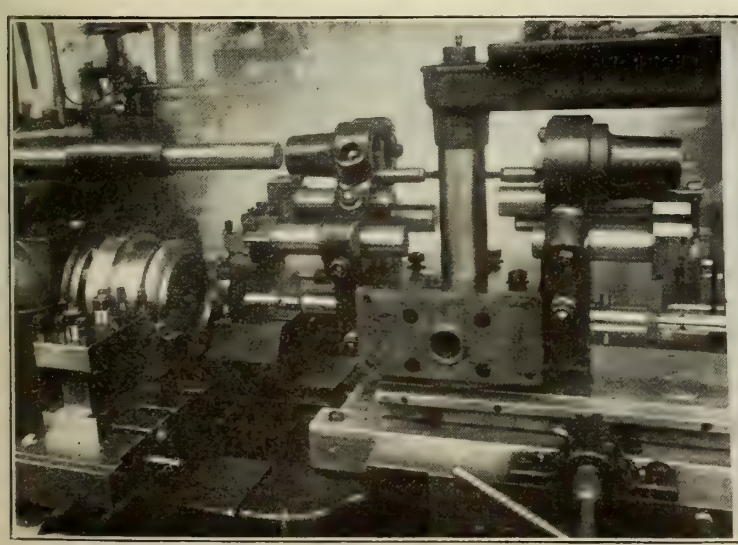
Tool No. 3 is a combination tool carrying a finish boring bar and three turning cutters. Simultaneously with this, the back cross slide operates and finishes the shoulder and the end. No. 5 is one of the standard boring bars with adjustable floating cutters, which are now rapidly replacing adjustable reamers. This sizes the hole very accurately and gives a highly finished bore with a minimum of trouble. The set-up for this operation gives a good instance of the use of the overhead support which is fitted to the machines. It consists of a bracket bolted to the headstock which carries a steel bar 2⅛ in. diameter. On each combination tool there is a pilot bush attached by three studs in clearance holes so that the bush can be aligned true with the overhead bar. It will be appreciated that this arrangement ties up the combination tool to the headstock very rigidly and enables coarser feeds to be used and a greater accuracy to be obtained than would be possible without it. It is especially useful when dealing with work having no through hole, where it is of course impracticable to pilot in the chuck, and on work where only a very small bar will pass through.

At the second operation the work is gripped in soft jaws and the only turret tool is a slide facing tool which provides another good example of its application. In this case two tool blocks are used, one carrying a roughing, and the other a finishing cutter. The face inside the work to be dealt with is comparatively narrow, and it is impossible to rough and finish with the one traverse, the roughing cutter being set to finish cutting before the finishing cutter starts. The machining time for the two operations is 23 minutes.

Operations on Bull Ring

Previous to the introduction of automatic turning machine methods, the bull rings were parted off from pot castings; they are now, however, made from separate castings. Chucking is done in stepped jaws and in the combination tool No. 1, Fig. 6, is a bar to which is clamped a double cutter boring head for roughing: this is positively fixed to the bar by a transverse pin engaging a slot in the head. It should be noted that two cutters are employed in the rough boring head, as the balanced cut helps to steady the work and a coarser feed can be used than with a single point cutter: the combination tool also carries a turning cutter for roughing the small diameter. Simultaneously with this the front cross slide comes in with three facing tools. It will be noted that here again a tool holder is employed for carrying some of the facing tools in order that they can be made from simple stock. No. 3 is a combination tool similar to No. 1 except that a single point cutter is used for finish boring, and there is an additional turning cutter. Simultaneously with this, the back cross slide 4 comes in and finish faces the three shoulders.

At the second operation, Fig. 7, the drawback arbor is again made use of for gripping the work by the bore finished at the first operation. Broadly speaking, the tooling is similar to that used at the first operation except that at the second the large external diameter has to be dealt with and the groove put in. In the combination tool No. 1 there are two additional cutters, one of which is used for turning the large diameter and the second for rough facing the end. The front cross slide No. 2 which operates simultaneously, carries the grooving tool and two facing cutters for the shoulders. Combination tool No. 3 finish turns the three diameters and simultaneously the back cross slide 4 finishes the three shoulders. The set-up for the second operation is shown in Fig. 8, the



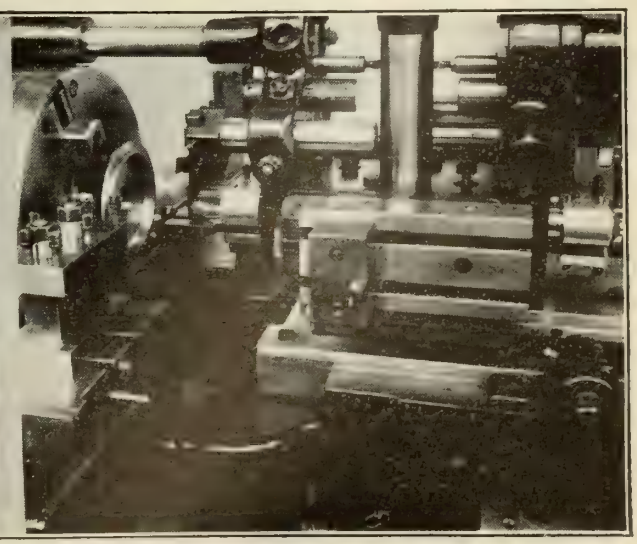


Fig. 8.—Left: set-up for machining bull ring (second operation). Fig. 9.—Right: set-up for first operation on valve head.

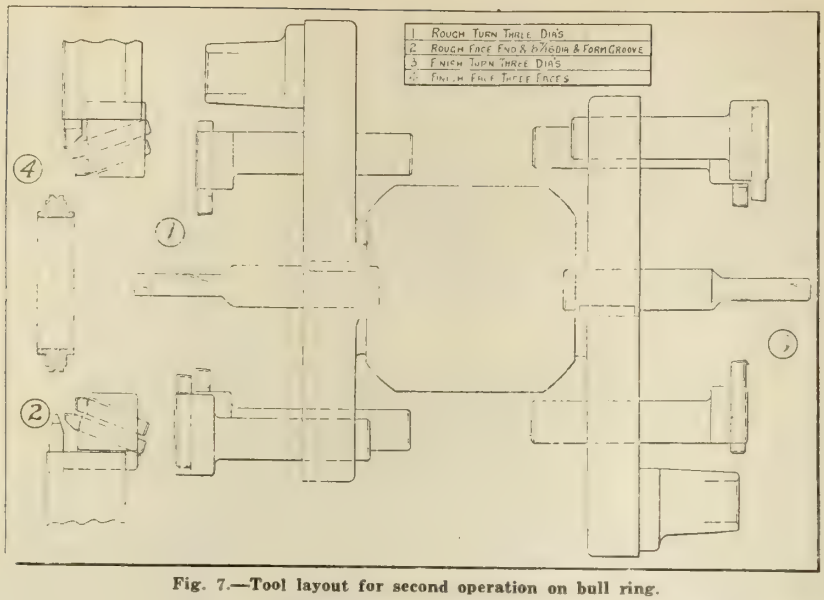

Fig. 7.—Tool layout for second operation on bull ring.

machining time for the two operations being 24 minutes.

Valve Follower

Valve followers are machined from mild steel stampings which at the 1st operation are gripped on the boss by special jaws in the Coventry chuck. The stamping sets back against the jaws which thus square it up and provide a support. The combination tool in the first position carries two turning tools and a patent straight flute drill with inserted spiral cutter. On the latter is mounted the same cutter head as is used for the bull ring; this now deals with the 6¾ in. bore. The slide facing tool in the second position carries cutter for facing the bottom of the 6¾ in. bore and the edge; it is pushed over by the front tool post which carries a cutter for facing the shoulder. The combination tool in third position is fitted with finish boring and turning tools while the slide facing tool in fourth position and back tool post finish the surfaces corresponding to those in second turret face. The set-up is shown in Fig. 9. At the second operation the machining consists of facing the boss and sizing the bore, the work being gripped in the 6¾ in. diameter by soft jaws. The boss is sized with the same type of tool as is used for the valve head. The machining time for the two operations is 22 minutes.

Piston Valve Cover

Another piece which is being successfully handled on the same type of machine is the piston valve cover shown in Fig. 10. The machining on this is such as can be explained without reference to a layout drawing. The casting is chucked by gripping on the boss. The first turret tool is a single point starting tool which opens out the core true for about ½ inch. The next turret face carries a combination tool with a four-flute core reamer and a turning tool for the 9½ inch diameter spigot. On the third turret face is a slide facing tool which roughs and finish faces, the two bosses being pushed over by the back cross slide which carries a tool for rough facing the large shoulder. Simultaneously the back cross slide comes in with a tool set ⅛ inch behind the rougher and finish faces the shoulder. On the last turret face is a combination tool which carries a bar for truing up the 2½ inch bore with a single point tool and a turning cutter for finishing the 9½ inch spigot. The machining time for the operation is 28 minutes.

Uniform Tooling Methods

In the layouts which have been described it will be noted that the cutting tools are of a very simple nature so that

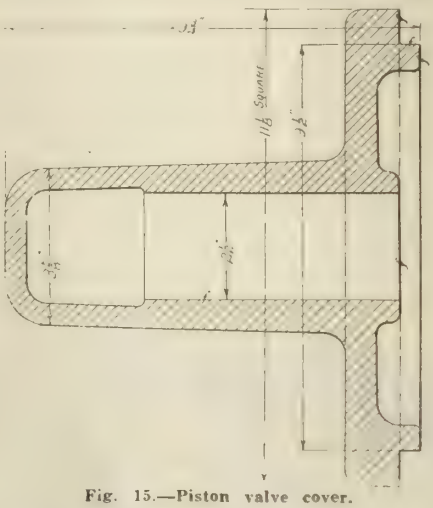

Fig. 15.—Piston valve cover.

consequently the cost of tool upkeep is low. Much of the prejudice which exists against automatic turning machines in their early days was due to a fear that they would be run inefficiently through lack of proper tool equipment. Standard tool outfits of wide general utility have, however, been developed by the manufacturers, to such an extent that with a proper equipment of these the laying out of operations for different pieces can be undertaken by anyone having a sound knowledge of ordinary turret lathe tooling.

It is important to note that the production times which have been given in this article are times on which the machines can be run in production, without repeated breakdowns for tool grinding; and on iron castings of average quality. Occasionally production times from other sources may at first sight appear better, but it should be borne in mind that much depends on the material which is being operated on, as some grades of cast iron are much softer than others, and can consequently be machined at higher speeds. These records were made on a special high-grade, hard, close-grained iron.

In these days of costly labour it behooves production engineers to explore all avenues which may lead to reduced manufacturing costs and whilst this article shows what is being done to this end in the locomotive industry by the use of auto lathes, the methods described are obviously such as can be applied in many other industries.

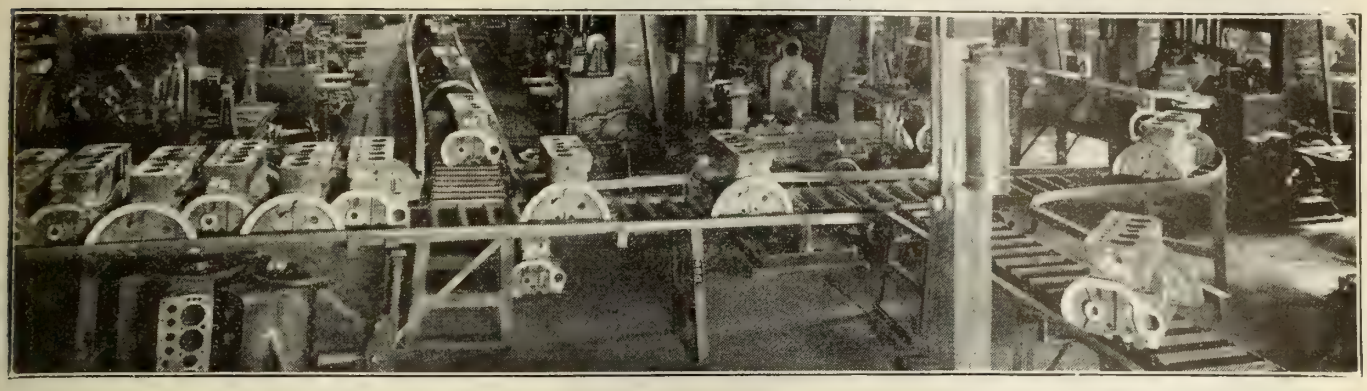
ORIGIN OF BALATA

The origin of balata gum, which forms the base of balata belting, dates back about 400 years. It was originally used by the Incas Indians to make crude suits of bull-hide armour, which they had to wear in order to protect themselves against the fatal effect of poisoned-tipped arrows. These suits of armour were composed of two plies of bull-hide, which were welded together with balata gum which they procured from the Bocla tree. These suits of armour were found by the Spaniards at the time of their conquest of that country and were subsequently transferred to European museums as historical relics. The balata gum used in the making of these suits of armour still retains its full strength unimpaired. The same result is obtained by using the Lanco impregnation process in the manufacture of balata belting.

BELT CONVEYOR SERVICE

Even in India, where the native labourers receive a very small wage, the belt conveyor is scoring in such work as unloading sand and brick from barges at the railway cars which stand alongside the slip, and also for loading sand from ground storage into bullock carts. The portable belt conveyors were equipped with a receiving hopper that would eliminate the necessity of placing the brick carefully on the belt, and they were thrown on the tail end where they could be conveyed into cars. These machines are operated by paraffin engines of 5 horsepower, and have given very good results. The belts are 25 ft. long, equipped with a 11 in. wide four-ply Goodyear rubber belt, and have a rated capacity of approximately 1 yard per minute. They are mounted on two wheels which are equipped with roller bearings, making it very easy for two men to move the belt to different parts of the yard.

Importance of Proper Routing Through the Plant



Showing gravity conveyor handling cylinder blocks.

By H. A. WILSON

ROUTING might appear at a first glance to be one of the points that could be classed as of secondary importance. However, in the present day of economic manufacturing, the subject has become of prime importance, especially in lines that are produced in great quantities. In fact in many factories the design and general layout has been very definitely influenced by the manufacturing plan of routing. In any factory it is rather difficult to isolate one particular phase of production and discuss it, to the exclusion of the several other interlocking problems. Some of these which are closely associated with efficient routing are, shipping facilities, natural lighting, amount of space available, etc.

The routing of materials through a manufacturing plant may be considered as a cycle. The raw materials enter at one point, circulate through the factory and return to that same point for shipment. The solution of the routing problem, expressed in a few words, is to have all raw materials enter the factory and pass through the various stages of manufacture, continuing to move in a general direction without unnecessary handling, or "dribbling back" at any time. The details of the problem are different in every factory and each solution requires individual and separate attention.

Basic Conditions

The primary factor to consider is that of receiving goods, and this point of origin, as we term it, is often the final stage in the routing schedule, as in most places goods come in over the railway siding and leave by the same route. When raw materials are received they are immediately checked into stores. Now store rooms should be adjacent to the receiving platform and also to the initial manufacturing operations so as to avoid useless trucking and handling. In some instances, where raw materials are subjected to widely differing preliminary handling and machining, it has been found convenient and economical to provide several store-rooms more or less widely separated, but adjacent to the manufacturing departments where the various raw materials are consumed.

Under the subject of basic conditions we must bear in mind that the finished product must return to its point of origin for shipment and that the receiving department must not be permitted to monopolize all the available space in the neighborhood of the railway siding, or the receiving and shipping platform.

Factory Construction

If the manufacturing is all done on one floor the problem is somewhat more simple than if several floors were utilized. In the one-floor proposition all materials can be conveyed progressively from one machine to another and travel toward the assembling department. From the assembling they would continue on through inspection and to the shipping department which would be beside the receiving department.

In the case of the factory consisting of several storeys, it has to be determined whether the preliminary operations could best be done on the ground floor or on the top floor, and then the subsequent operations must be classified as to floors. With this accomplished the individual routing schedule for each floor is devised.

Method of Transporting Materials

The hand-operated truck was perhaps the first piece of equipment to be used to transport material in a factory. From such a simple apparatus there has been developed many more modern pieces of equipment, such as the travelling crane, the overhead track, the gravity conveyor, the belt conveyor, etc. Travelling cranes are only used where large, bulky, and heavy equipment is being handled. The overhead carriers are used on a variety of articles, and are of value because they can be arranged to carry a very wide range of material.

Belt conveyors are used for handling such articles and materials as grain, sand, gravel, and all kinds of crushed or powdered materials. The gravity conveyor, however, is the most important factor in routing in any modern factory. Except in some unusual or special instance no power is required to operate the gravity conveyors. The special instances referred to, are met when a factory occupies several storeys and an initial step in the routing is to elevate all

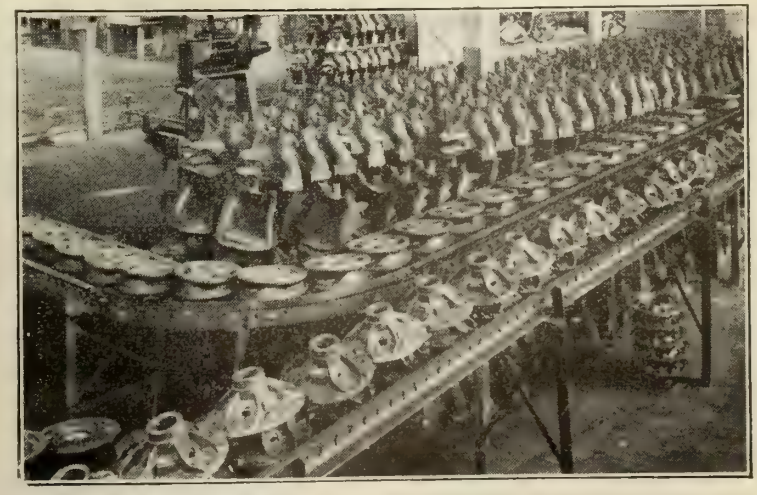


Fig. 1.—Handling differential carriers and transmission covers from storage to machines.

Illustrations through the courtesy of Jones and Glasco, Canadian agents for the Dow Co.

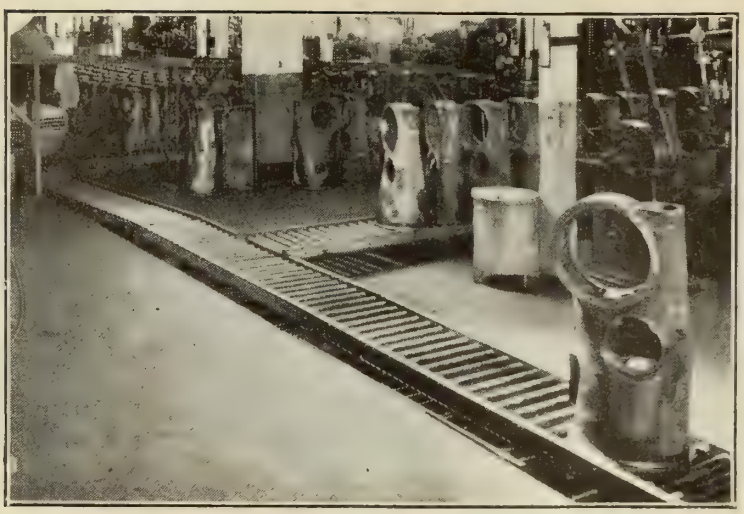

Fig. 3.—Showing gravity conveyor handling heavy transmission housings between machine operations.

material to the top storey, or when an insufficient height is overcome by a direct lift to a gravity line.

Machine Shop Applications

Probably the automotive industry furnishes us with the best example of production work in manufacturing plants. In no other line of machine shop activities does routing assume the same importance. Practically the whole shop is built around a production schedule. Of course these automotive shops were not always models of efficiency and thus some interesting comparative production figures are available. In the old days work-in-progress cluttered up the surplus floor space and encroached on the aisle space. Men were busy with hand trucks moving pieces of work from machine to machine. To save time, equipment was placed so that batteries of machines handling successive operations were adjacent to one another. Still it was evident that a great deal of floor space, man power, and material were being wasted and conveying systems became a necessity. Meanwhile, with these improved methods of handling work, in conjunction with improved machinery, the production per man per day increased two hundred per cent. and more, in a decade.

Conveyor Installations

Fig. 1 illustrates a gravity conveyor system handling differential carriers and transmission covers from storage to machines. It will be noted that the floor space is comparatively free from castings and work. This equipment is capable of handling vast quantities of these pieces without congestion.

Fig. 2 shows another installation of gravity conveyors transporting cylinder blocks from one location to another. There are numerous operations on various machines on these castings and records show that when these blocks were "man-handled" the time of transporting some was almost as great as the machining time. With this system in use, no man-power is required and there is only a nominal overhead charge to be reckoned with, while the capacity of the conveyor is in excess of all possible requirements. Here again the floor space is not monopolized.

Fig. 3 illustrates the conveying of heavy transmission housings from one machine operation to another. If this illustration is studied it will be seen that the piece would be an awkward one to handle by other means, especially if the production was large.

Fig. 4 illustrates an installation of conveyors in a shop where a large number of machine tools are installed. Miscellaneous castings are being handled on a double line of conveyor, having two different elevations.

Fig. 5 illustrates another special type of gravity conveyor with 1 1/16 inch diameter rolls handling crank shafts in a vertical position.

Reducing Idle Time

The above illustrations only go to show how closely the routing problems are tied up to transporting and conveying problems. The present high rates paid to mechanics and operators make it imperative that this class of labor be employed sixty minutes every working hour. If routing conditions are not good, congestion and delays frequently occur, and idle time results. This idle time adds to cost of production and cuts down profits.

The subject is a very broad one and there are many interlocking factors. It is very difficult to express in figures just what savings can be made. Men who have studied the problem from all angles, and whose experience covers a score or more of years, state that actual savings of twenty-five per cent, are frequently made in factories that were considered reasonably well laid out, to begin with.

Of course the ultimate has not been reached and in every factory certain compromises have to be made in developing a routing schedule. The problem is one that is never finished, particularly in a growing business.

CUTTING STEEL BARS

One of the most ordinary processes in engineering ships is the cutting up of steel bars. As usually performed, the process is very uneconomical, especially when a large number of pieces of the same size have to be cut off. In order to get over this difficulty a British firm has introduced a new method which enables several bars to be cut simultaneously. A feature of the machine lies in the vise, which has two jaws, one moving horizontally and the other vertically. The machine is designed to cut off a six inch bar, and by the use of the special vise it can cut off three 4 inch bars, or seven 2 inch bars, and so on at one time. By an ingenious arrangement the saw is never engaged on the full thickness of all the bars at the same moment. This enables a high speed of cutting to be maintained. An incidental feature is the use of a revolving mechanism, which removes all the chips from the saw. As an indication of the speed at which this machine will work it may be mentioned that three 4 inch bars were cut through in less than ten minutes.

Multiple Spindle Milling on Vertical Machine

Demand for Greater Production Calls for Tools of Higher Efficiency—Rotary Table Allows for Continuous Operation—Roughing and Finishing Performed at the Same Time

WITHIN the past few years the development of the milling machine has demonstrated the rapidly increasing application of this type of equipment to the solving of many of the more intricate problems related to general shop practice, where greater production is a vital and ever-present question. This method of surfacing metal has an almost unlimited field and it appears to be largely a matter of design in order to obtain a machine that will take care of an every increasing range of requirements. Where it is a question of quantity output on any specified class of work the construction of a single purpose tool to handle the work is a profitable proposition as machine adjustments are reduced to the minimum, and the greater percentage of operator's time is utilized in actual production. However, it is only a comparatively small number of plants that can provide sufficient work for the constant operation on one particular so that the selection of any machine must be based on its serviceableness to a varied range of work.

Speeding-Up Production

It may be true that the single spindle machine can be adapted to a greater variety of work but as a production unit on many similar parts its ultimate efficiency is undoubtedly restricted. The tendency is to develop tools that will be constantly engaged and in such a way as to minimize the idle production time between the actual cutting operations. From the single spindle machine which featured the design of early milling machines the multiple spindle type of the present day provides an interesting development in the cutting of metal with a multiple arrangement of tools or cutters. The multiple spindle type of milling machine provides for the roughing and finishing of many surfaces during the one continuous movement of the work beneath the cutters. The rotary table, equipped with special work holding fixtures, permits parts to be placed in position and removed after machining without the necessity of stopping the machine. The production is therefore dependent on the steady supply of raw material to the machine.

Milling Connecting Rods

Four good examples of machining parts on the heavy duty knee type of milling are shown in the accompanying illustrations. Fig. 1 shows a rotary continuous milling machine set up for performing the roughing and finishing operations on both sides of each end of connecting rods for International Harvester Motors. It will be noted that the work holding fixture is made exceptionally high to permit of using the extra cutter head for milling the lower portion of the outer end of the connecting rod. The outer spindle extends down into the centre of the fixture and spaced cutters take care of both faces of the rods.

The design of the fixtures is very often an essential factor in meeting production requirements, as adequate clamping and locating facilities are imperative where standardization is desired. Owing to the continuous movement of the rotary table it is important that the parts be inserted and secured in position with the greatest convenience and assurance of rigidity and accuracy.

Motor Frames

Surfacing the bases of electric motor frames is shown in Fig. 2 at the right. The fixture used for holding the part is of hexagon design capable of carrying six frames. The method of operating the clamping devices is illustrated at the extreme left. The central bolt is hinged at the inner end to a plate secured to the face of the fixture by means of four bolts. On the outer edge of the base is supported a swinging yoke that carries the three-point clamp that bears against the outer edge of motor frame. It will be seen that the clamping nut is of small size to allow the frame to be passed over, the slotted clamp allowing free passage over the body of the bolt. In this way it is not necessary to remove the nut when placing the work in position. One spindle is fitted with a roughing cutter and the other is used for finishing. The production time on this particular piece is one frame a minute, or a complete revolution of the table every six minutes. Machine is operated continuously, work being removed and located while table is in motion.

While this fixture was primarily designed for this particular job, it will be noted that the plates on each face are detachable, so that a slight modification of the clamping members will permit of using the jig for work of a similar character.

Three-Spindle Machines

Two three-spindle machines are illustrated in Figs. 3 and 4. That at the left is operating on cylinder heads for Buda

Illustrations supplied through the courtesy of The Ingersoll Milling Machine Co., Rockford, Ill.

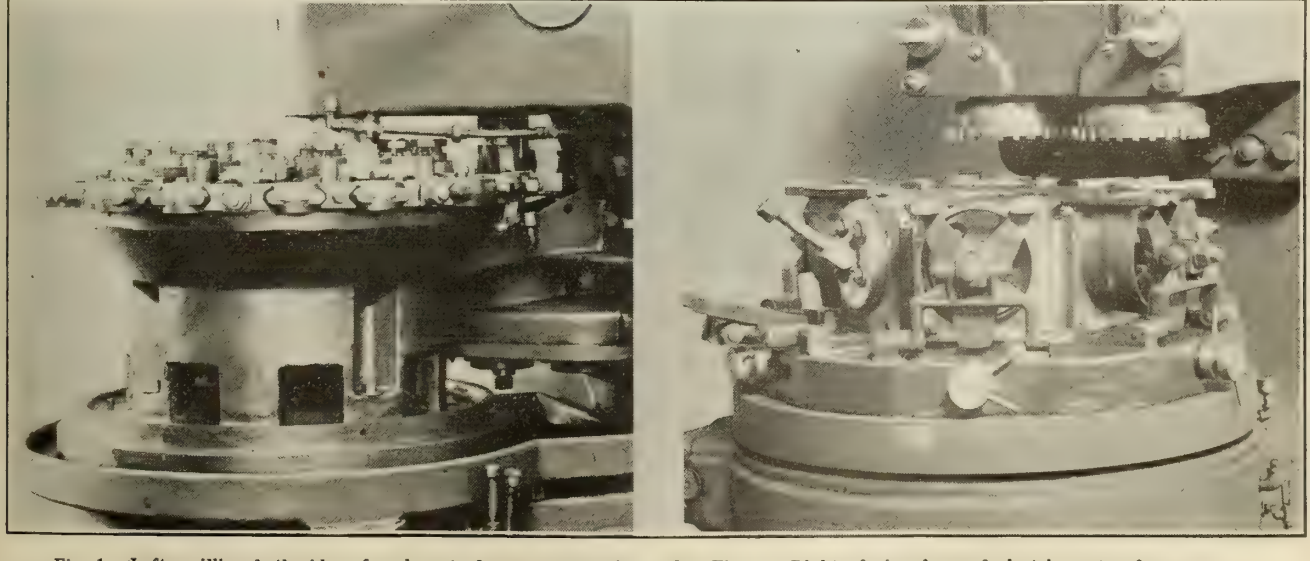

Fig. 1.—Left: milling both sides of each end of motor connecting rods. Fig. 2.—Right: facing base of electric motor frames.

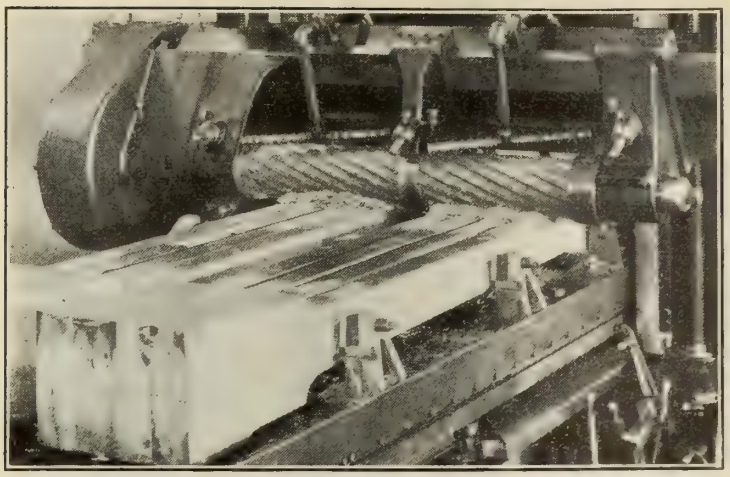

Fig. 5.—Edging eight locomotive main rods.

Motors. The work holding fixture is of simple yet interesting construction. As is general with jigs of this nature it is of the single purpose type. Four locating stops are arranged in the centre of the base to support the inner edge of the casting. Two swinging clamps are used for holding each piece, these being directly in line with the rear locating block to avoid any possibility of springing the work. A coil spring is placed on the clamping bolt so that the reaction when the nut is released frees the clamp from the work. Height stops and thrust stops are likewise provided. The two left hand, small-diameter cutters are used for roughing and the large cutter, in its passage over the work finishes the entire surface. Where surfaces are to be in the same plane it is advisable to finish same with one cutter.

Fig. 4 shows a similar machine milling the sides of flywheel housings for automobile motors. Again a fixture of special design is used, in this instance the work being placed on two sets of stops, one set at the base of the work and the other inside the casting extending up to the inner edge of the surface to be milled. The clamping is accomplished by gripping the protruding lugs. Places for three castings are provided on the fixture. This machine has three spindles, two with small cutters doing the roughing and the large one for finishing.

Locomotive Main Rods

An excellent example of heavy duty horizontal milling is shown in Fig. 5. This cut illustrates a 75 h.p. milling machine edging eight locomotive main rods, taking a cut ¼ in. deep and using a table feed of 8½ in. per minute. Fifty-nine and one-half inches of steel are being removed each minute, and it is necessary to use 68 h.p. to accomplish this work; one and one-quarter horsepower per cubic inch of metal removed. The machine is equipped with special rod fixtures, universal for all locomotive rods. The cutters used are 9 in. by 24 in. Ingersoll helical inserted tooth slabbing type. The tail support and intermediate steady head are adjustable along the cross rail so that a wide range of work within the capacity of the machine is possible. Adjustable brackets are provided for supporting the pipes that carry the cutter lubricant.

Keep Cutters Sharp

Too much stress cannot be laid on the importance of maintaining a keen edge on milling cutters. It is a wasteful and expensive practice to try and retain an efficient set of cutting tools without suitable equipment for keeping the same in good working condition. Cutters to be really "sharp" must have the proper clearance. Too little clearance will cause the teeth to drag and absorb power that should be used for cutting; too much clearance will cause the tool to chatter and result in inefficient production. Cutters should be ground so that every tooth has the same rake and clearance angle; thus distributing the cutting action uniformly among the teeth in the cutter.

GRINDING STAINLESS STEEL

Tests show that annealed stainless steel, under constant feed, developed the highest grinding resistance of any metal tested. Wheel wear, when rough grinding it, was excessively high and the wear continued high even with hard wheels, because the clearance between grains was insufficient and loading increased. Hardened stainless steel also caused considerable wear when fairly heavy feeds were taken. Also, if light cuts are employed, as for finished grinding of a flat surface, the hardened stainless steel has a tendency to burn.

EFFECTIVE BELT SPEED

Practice is still rather uncertain about the ratio of horsepower and belt width, despite the many views—or, perhaps, in consequence of the many views—expressed by investigators. Wider belts for heavier loads sums up the apparent requirement. Speed investigations recently were expressed in the formula that belt speed is almost exactly in proportion to the width of the belt. In relation to high speeds the effect of centrifugal action must be considered, and the conclusion is expressed that nothing is gained by operating a belt in excess of 4,000 ft. per minute, an dthat at 5,000 ft. the particulars given, that horse-power increases directly as to speed up to 4,000 ft. per minute, and that at 5,000 ft. per minute the effective tension or pull is reduced about 10 per cent. The preference should be for a maximum of 4,000 ft. To secure transmission at a higher speed it becomes necessary to increase the tension of the belt to a point beyond economical operation.

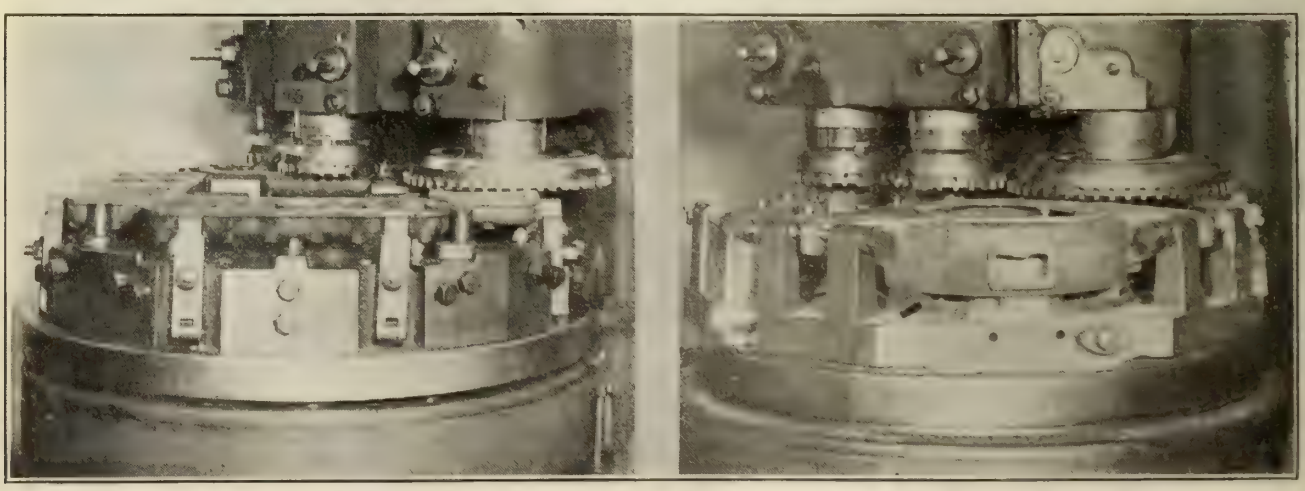

Fig. 3.—Left: roughing and finishing motor cylinder heads. Fig. 4.—Right: roughing and finishing flywheel housings.

Duplicate Pieces Machined by Automatic Milling

Constant Fast Travel Between Cuts—Automatic Change to Variable Cutting Feed—Standard Vise Fitted With Special Jaws Used for Work-Holding Fixtures—Milling Bolt Heads

INCREASED demand for more economical production is an influencing factor in the development of machines requiring the least amount of human attention in their operation. Today we find manufacturers availing themselves of every opportunity in the installation of automatic machinery in an endeavor to reduce their manufacturing costs and increase output. Automatically controlled equipment is the logical consequence of the efforts put forth by engineers to meet this growing requirement. The Brown and Sharpe Mfg. Co. has produced a special knee-type automatic machine for the milling operations on a wide range of parts within its capacity.

Squaring Bolt Heads

The illustration to the left shows the machine adapted to the squaring of bolt heads. In this instance in order to mill the four sides of the bolt head uniformly it is necessary to employ standard index centres. These are set for rapid indexing and the operator has only to withdraw a locking pin and give the hand wheel a quarter turn. At the completion of the cut both the spindle and the table stop. The machine is set to operate semi-automatically, as the loading time is slightly in excess of the cutting time and a much higher production per hour may thus be obtained than if operated fully automatically. As the fixtures are set as close together as possible that the non-cutting travel of the table may be reduced to a minimum, the stopping of the spindle and table is also a safeguard to the operator when loading and unloading the fixtures. For such operations it will be noted how conveniently the control levers are arranged and the ease and speed with which they may be operated.

These bolts are made of steel and the operation consists of straddle milling the sides of head at two index settings of the chuck. Cutter spindle operates at 101 r.p.m. under a feed of 4.6 in. per min. The length of cut is ⅝ of an inch, the cutting time for each pair of sides being 8½ seconds, giving a total time of 23 seconds for each bolt head, including the fast travel speed of six seconds. Production is at the rate of 156 bolts per hour. The top surfaces of these bolts are milled by a method similar to that used for the pump bodies shown to the right.

Facing Pump Bodies

The right-hand view of the accompanying cut clearly illustrates the adaptability of the vertical spindle attachment to the milling machine. A large inserted tooth milling cutter is rotated in the same direction for both cutting operations At the finish of each cut the spindle is automatically stopped upon the reversal of the table, thus eliminating the possibility of marring the work when the table moves at its constant fast travel, in bringing the other fixture up to the cutter. It will be noted that the extreme left-hand table dog is about to engage the plunger, stopping the spindle, reversing and throwing the table into its constant fast travel. The operation is a completely automatic one —the operator only loading and unloading one fixture while the cutter is engaged in milling the part in the other. The fixtures are of simple construction, being the regular standard vises fitted with special jaws. These pump bodies are made of cast iron and are milled on the face shown at a spindle speed of 53 r.p.m. The table travels at a speed of 4.6 in. per min. The cut of 2.75 in. is performed in 37 seconds, with a constant fast travel between the two pieces of 3 seconds. The total time per piece is 40 seconds, giving an output of 90 pump bodies per hour.

Operating Features

In the operation of this machine four different styles of table dogs are required to obtain all the automatic movements of the machine. These table dogs are located as shown in a tee-slot on the front face of the table and actuate the two sets of tripping plungers located on the saddles, causing the necessary movements that operate the mechanisms contained in the reverse gear and feed cases.

This motion is transmitted to the cases by telescopic shafts, one end of each of which is a part of the hand control levers on the front of the machine When reversed the table always moves at its constant fast travel.

The constant fast travel is obtained through hardened spiral gears and the variable cutting feed by means of a worm gear. By the action of a cam and the operating clutch the change is made from one to the other automatically. To provide for maximum efficiency the hardened and ground steel shafts operate in phosphor bronze bushings and journals are fitted with ball thrust bearings.

Overcoming Difficulties in Babbitt Bearings

Proper Temperature of Mandrel—Coarse Granular Structure—Blowholes in Linings—Uneven Wear—Effect of Too Much Dross—Shrinkage of Shell—Two-Part Split Bearing

By W. S. STANDIFORD

IN the previous part of this article the author dealt with babbitt in general and the method adopted in overcoming different faults in bearing practice. Here he deals with a number of difficulties and their respective remedies.

Difficulties and Remedies

Difficulty.—Blisters on solid one-piece and also two-part bearings.

Remedy.—These blisters are caused by a workman putting oil on the mandrel so as to prevent the latter from sticking to the finished casting. They occur mostly on one-piece castings, although the two-part ones will show this defect if oil is used. Their size varies with the amount of oil put on and its viscosity. Rub flake graphite over mandrel's surface that is in contact with the hot metal, don't use oil for this purpose. If no graphite is handy, use a very thin coating of white lead and let it dry before use. Two-part shells, in most cases, will not need any graphite or white lead on mandrel as the latter can be easily removed when the metal is cold enough to handle. The mandrel ought not to be taken out of contact while the casting is hot, as warping and hollow cavities will be the result of such treatment.

Difficulty.—High-grade babbitt casting has large numbers of hard and soft spots and it has a dirty-looking, casted surface.

Remedy.—Cold babbitt that has been solidified in the melting pot, has been heated too rapidly by the workmen trying to hustle along the work. The lighter metals in its composition rises to the surface and become oxidized by contact with the air, while the heavier ones sink to the bottom. Pouring under the above conditions makes a series of hard and soft spots. Slower heating, more stirring, and the use of a layer of charcoal or sawdust on top of the molten mass, will produce a uniform wearing casting.

Difficulty.—Extreme shrinkage of high-grade babbitt castings in bearing shells resulting in loose bearings, broken anchors and porous areas. The metal will also be found to be oxidized, softened and dirty, and its antifrictional qualities destroyed.

Remedy.—The above is one of the cases in which the employees put the blame on the metal's quality as being of an inferior grade instead of their own fault in handling. This condition of babbitt is due to the fact that it was heated and poured at too high a temperature; thus burning and oxidizing some of the more fusible metals. Careful attention to the proper melting point and also to the mandrel's and shell's temperature and use of charcoal on babbitt's surface, will obviate this trouble. All babbitt metals of the various grades on the market ought to be heated to such a temperature so that it will just char a stick when it is plunged into it and instantly removed. This is a rough-and-ready shop method, but effective just the same.

The proper temperature of any mandrel is shown to be just right when a drop of water will evaporate quickly from its surface without spluttering, the heat of the mandrel being about that of boiling water. Never allow any babbitt of the various grades that are used in factories to get red hot in its melting pot as it will be ruined. Some workmen have the habit, when doing work among crowded lines of machines in factories, of locating their fire too far away from their place of work and then running with it to the machine, expecting it to have the right temperature for pouring and making good castings when they get there. This is bad practice, as it causes the finished work to contain all of the above defects enumerated. The proper thing to do in cases of this kind is to shut down the machine that is next to the one requiring rebabbitting, or better still, if it can be done, to have a small stock of finished bearings in the stockroom and insert one of them in the machine thus keeping the latter out of operation for as short a time as possible. Should it be impossible to do so on account of circumstances, bring the portable forge used in heating the metal as close to the machine as possible so as to avoid burning of the babbitt.

For field work of this character it is much better to **use a tin base alloy**, as it is much better suited for field work than a lead base one on account of its capability to withstand more abuse than the lead base material. Of course, it is understood that abuse of any babbitt metal is deprecated, but as long as the "human element" is in charge of machinery repairs, precautions ought to be taken by executives to help matters along by purchasing a suitable grade of metal and impressing upon their workers that care must be used.

Coarse Granular Structure

Difficulty.—The lining has a coarse granular structure, it looking as if sand has been added to it when melted. **Remedy.**—This coarse granular structure is due to babbitt having been heated and poured into lining shells at too low temperature. The latter should be just right for good results. Too low heating of babbitt is mostly done by **"workmen who watch the clock and wish to quit when the whistle blows;"** although it occasionally happens through carelessness of workmen in desiring to get a disagreeable job done quickly when they are working in a place where there is not much light.

Difficulty.—Numerous blowholes in linings, the latter shrinking away from the shells when metal is cold. **Remedy.**—this is a case in which the heat of the melted babbitt is correct, **but the shells and mandrel are too cold.** Proper heating of both shells and mandrel will cure this defect. If blowholes are still plentiful after application of the above remedy, have more air-vents when pouring the hot metal; a lack of air-vents will make the molten babbitt bubble and prevent some of the bubbles from escaping.

Uneven Wear

Difficulty.—Linings soft at tops and brittle at their bottoms thus wearing unevenly. **Remedy.**—Shells and mandrels are too hot, the result being that **the hot babbitt is made to cool too slowly**, which allows the heavier ingredients to sink to the bottom of lining while the lighter ones remain on top. Proper attention to heating and other details will remedy this state of affairs.

Difficulty.—Spongy and dirty looking castings when metal and mandrel and also shells have the right temperature. Remedy.—Too much dross was allowed to get into melted babbitt while pouring. Workmen should always dip ladle from the bottom of the pot so as to avoid getting too much of the surface metal. Use a self-skimming ladle having a spout so shaped as to pour a round thick stream instead of a wide flat one. Such a ladle will prevent the castings, to a large extent, from being spongy and dirty. A broad, thick stream which is poured intermittently and slowly, will also produce porous areas and blowholes, **the air oxidizing the babbitt surface.** The latter ought to be poured in an even, steady stream without surging in ladle, as surging forces dross into the castings. Spongy and dirty castings are many times caused by workers throwing too many pieces of solder into the babbitt melting pot. All small pieces of solder should be saved for future use in soldering, and be remelted into long sticks, an angle iron mold making a very desirable stick; all lengths of stick can be controlled by clay spacing the iron into sections.

Shrinkage of Shells

Difficulty.—Too much shrinkage in shells when using a low grade babbitt, temperature of metal, lining shells and mandrel being just right. Remedy.—If much low grade metal is used as a lining

it is best to employ a much smaller diameter mandrel; then take a round-faced hammer, and starting in the centre of casting tap it lightly along its centre, extending the blows gradually up both right and left hand sides until the top is reached. This hammering process spreads the metal sufficiently so as to make it fit the lining shells. Next, bore in a boring mill or scrape to size. This method, though effective, is not to be recommended for continuous use as it **wastes too much time and money, but it will do for emergencies when breakdowns occur and a factory is caught without a supply of higher grade metal, which obviates this trouble,** it being best at all times to purchase the best grade babbitt.

Split Bearings

Difficulty.—Small two-part split bearings made out of lead-base babbitt have a spongy surface on shaft bearing part. Heating of shells, mandrels and babbitt being correct. **Remedy.**—This is due to the fact that the shells have been poured with their mandrels on top, thus allowing a certain amount of dross to fill up the part of shell in contact with the revolving shaft; a lead-base alloy generally has more dross to it than a tin-base one. These small two-part bearings are best poured in a horizontal position, bottom upwards (which causes any dross to rise to the top and makes it stay next to the bottom of the shell when casting is done), the mandrel resting on a surface plate and the molten metal poured through holes in the bottom of shells. This method of working has the great advantage of making the bearing surface very clean and dense, the babbitt is compressed by the weight of metal on its top, which faces the bottom of shells, an impurities or dross thus remaining bottom part of the finished casting

In the pouring of large 2-part bearings using the same quality lead-base alloy, as in the small bearings listed above, it is much better practice in order to get sound castings, to have the shell and mandrel in a vertical position, the front bearing surface facing downwards. This causes any dross that will form to rise to the back end of the casting part which faces toward a shaft's end so that there will be a thin layer of dross that can be cut off if proper allowance has been made for extra metal. These large bearings can also be cast bottom upwards like the small two-part ones, but, as a general rule, it will be found much more convenient to do this pouring with the shells in a vertical position.

Bronze Linings

Difficulty.—Babbitt will not stick to bronze lining of electric motor shells, mandrels, hot metal and shell temperature being right. **Remedy.**—The part of the shells where the hot babbitt touches them ought to be tinned with a thin film of half-and-half tinners' solder, using a flux of chloride of zinc. The hot babbitt coming into contact with this solder's surface will melt the film and effect a firm junction between the two metals. **Under no circumstances should the soldering flux be added directly to the melted babbitt as it doesn't work well with it and causes trouble.**

Difficulty.—Workmen trying to make babbitt stick directly to iron shells by tinning the latter with solder in order to do without anchors, everything else being at the right temperature. **Remedy.**—The sticking together of cast iron shells and babbitt cannot be depended upon, as these metals do not alloy at the molten solder's temperature, it not adhering to the shells when cold. Should a higher heating of the babbitt be tried in order to effect a junction, the solder will be oxidized and the babbitt's quality ruined with no adherence between the iron and babbitt taking place.

Difficulty.—A lead-base alloy refuses to give satisfactory service on factory machines with hot metal and shell heat being correct. **Remedy.**—It is evident from the above state of affairs that too much vibration of moving parts is the cause of this very rapid wearing of metal, a lead-base mixture proving much too soft a metal for use on such type of machines. A tin-base alloy, one that contains a very high percentage of tin and antimony, will work well and prevent trouble of this kind.

Difficulty.—A high grade babbit wears unevenly and is very brittle, crumbling like granulated sugar in spots. **Remedy.**—Workmen, having burnt overheated babbitt in a ladle, have attempted to restore its quality by adding new metal to it. Such a mixture ought to be thrown away as it cannot be restored. Care should always be observed in the heating and handling of babbitt of any grade so as to avoid such a waste of money. Quick and rapid methods of doing repair work is the rule nowadays, and any method that helps to reduce the time taken in getting various classes of machines into operation after breakdowns always meets with a warm welcome by employers, as machinery breakage will occur at the most unexpected times.

(To be continued.)

SQUEAL OF A LEATHER BELT

There is one characteristic of the leather belt which has not been given the prominence to which it is entitled, and that is the habit the belt has of squealing whenever it slips. Whenever a leather belt, travelling even at a moderate rate of speed, slips on the pulley, whether it is because of an excess load, or because of reduced tension resulting from the slackness of the belt, whenever this slippage passes a certain low point, the belt emits a sound very much like a squeal. This is noteworthy because this squeal is not characteristic of other forms of belting, which, in fact, may slip very greatly without making any sound.

It is not known at what point the leather belt will begin to squeal. The slippage of the leather belt transmitting its load under favorable conditions is usually about 1½ to 2 per cent. Of this amount some considerable part is recognized as "creep," as distinguished from the real slipping of the belt on the pulley, and actual slipping does not begin until after the full effect of creep has been registered, so that a slippage of 1½ per cent. or 2 per cent. is made up of all the creep of the belt and some little slip. The belt will not begin to squeal until it begins actually to slip, and possibly this point would vary in different belts with different classes of surface or finish, and also with the different conditions of tension, load, etc.

But the point to be emphasized here is the fact that the leather belt will not slip to an extent to impair its transmission qualities without giving due notice of the fact, without signalling a note of warning. This is characteristic of leather belting. The eye cannot detect the diminuation in speed of either the belt or the driven pulley, and many a belt owner, with the belt running directly before his eyes, may be robbed of power as represented in the diminished speed of his machine, unless he takes warning of the "squeal" that registers excessive slip.

EMPLOYMENT AT HIGHER LEVEL

Higher than at any time since the middle of December, was the level of employment during August, according to statistics of the Department of Labor. The record was over 7 points above that of August 31 of last year. Reports were received from 4,019 manufacturers employing 420,879 persons, as compared with 416,699 employees on July 31, an increase of 4,180 workers or 1 per cent. Automobile, fruit and vegetable factories, copper smelters and refineries, tin can, boot, shoe, fur, pulp, paper, tobacco and electrical apparatus works were considerably more active. On the other hand, contractions were evidenced in saw-mills, rubber, textile and petroleum product factories. The tendency during August of last year was downward, the closing of the railway car shops at the end of the month having affected employment materially.

In the iron and steel industry, the resumption of operations in automobile plants temporarily closed at the end of July, caused fairly large increases in staff, which were supplemented by gains in the employment afforded in steel shipyards, machinery, iron and steel fabrication works and foundries. The production of agricultural implements, crude, rolled and forged products, and weighing and measuring instruments, on the other hand, showed a decline. Firms in all provinces except the Maritimes were decidedly busier and in that district the contraction was chiefly due to a partial shutdown in the Sydney district. Reports received from 724 concerns indicated a total pay-roll of 112,819 persons as compared with 110,106 employees at the close of July, a gain of 2,713 workers, or 2.5 per cent. The tendency at the end of August, 1921, had been distinctly downward as the railway car shops had reported one of their frequent shutdowns.

Producing Heavy Parts on Automatic Turret Lathe

Operator Must Understand Machine Thoroughly—Special Instruction for Operators—Advantages of Eight-Faced Turret—Operations on Differential Carrier—Length of Cut Regulated by Timer Dial

IRRESPECTIVE of the type of machine, production is largely dependent upon the knowledge and ability of the operator to get the most out of it. It is essential for him to understand its construction and to keep it properly adjusted and in good working order. The machine with the best production record will invariably be one that is operated by a man who has made a special study of its design and arrangement and manipulation of the different mechanisms. The intricate and accurate construction of automatically operated machines requires a specially trained man in charge of its operation. It is now the practice of many large manufacturers of automatic machines to provide special instruction to those desiring to operate this class of machine tool equipment successfully and economically.

Duties of Operator

An operator must be able to approach his work with the greatest degree of confidence, so that every move will be a well ordered detail in the necessary cycle of operations required to produce the part for which the machine is being tooled. He must know how to adjust and care for the machine so that delays due to break-downs, which cause loss of production, will be minimized.

The grinding of the cutting tools is very important as the automatic feature necessitates that continuous operation be carried on without interruption. Not only the grinding but the setting and arrangement of the tools in their respective positions should be carried out without hesitation. Special application to this problem will result in a fuller realization of doing things promptly, neatly, accurately and quickly. Many graduates from these manufacturers' instruction schools have been able to double their former production, and in several cases, the increased output has been greater even on work which they thought was already being produced at a very good rate.

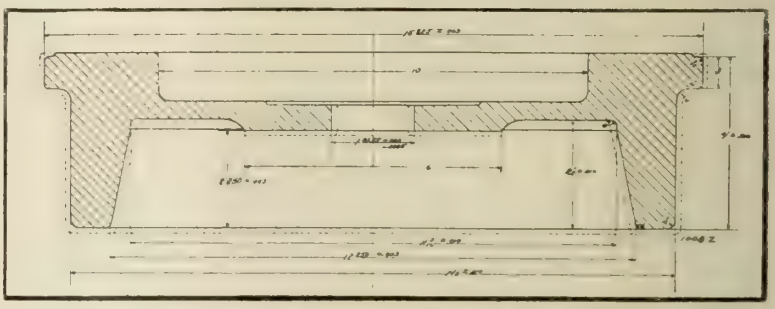

Fig. 2.—Sectional view of automobile flywheel.

Machining Flywheel

The advantages of the eight-faced turret are clearly indicated in Fig. 1, which illustrates an aeroplane view of the set-up for machining the cast iron flywheel shown in Fig. 2. In the arrangement of the different tool holding fixtures that are attached to the various faces of the octagon turret it is necessary to consider the successive stages of machining so that the cutting of the metal will be accomplished in the most economical and convenient method. The sequence of operations in the production of the flywheel here shown are: (1) The piece is held with hardened jaws in a three-jaw chuck and supported at the back by using chuck jacks. (2) The face of the hub B is machined with tools held in a sliding block on the first turret position, at the same time the three faces E, H and J are roughed off by the respective tools in the front tool post. (3) The second turret face supports the fixed bar that carries the flat cutters for roughing the bore and face of the hub. (4) Side 3 of the turret supports the large combination tool block that carries the tools for initial roughing the taper on inside of rim, the outside diameter G and the flange I. (5) The fourth index position of turret carries the boring bar and facing tool for finish turning the bore and face C. (6) The final reaming of the bore is accomplished with the reamer held in the fifth turret face. (7) Final roughing of D, G and I is performed by the tools held in the large tool block fixed to the sixth turret face. (8) The final operations at this setting are accomplished with the head on side 7 of the turret; these tools finish the inside taper and the two outside diameters, while the face E and shoulder H is machined with the tools held in the rear tool post.

The front and rear tool blocks are mounted on the cross slide and are adjustable to each other. Special tool holders can be mounted on top of either block, or a special block substituted in place of the standard one.

The finished diameter of the flywheel flange is 15.325 in., and that of the main portion 14.125 in., with a variation allowance on the flange of .003 in. and .010 in. on the wide section. The bore is finished to a diameter of 1 9375 in. with a low tolerance of .0005 in. The surfaces machined are shown by the dotted lines in Fig. 2, and the floor to floor time is approximately 14 minutes.

An interesting turret lathe operation

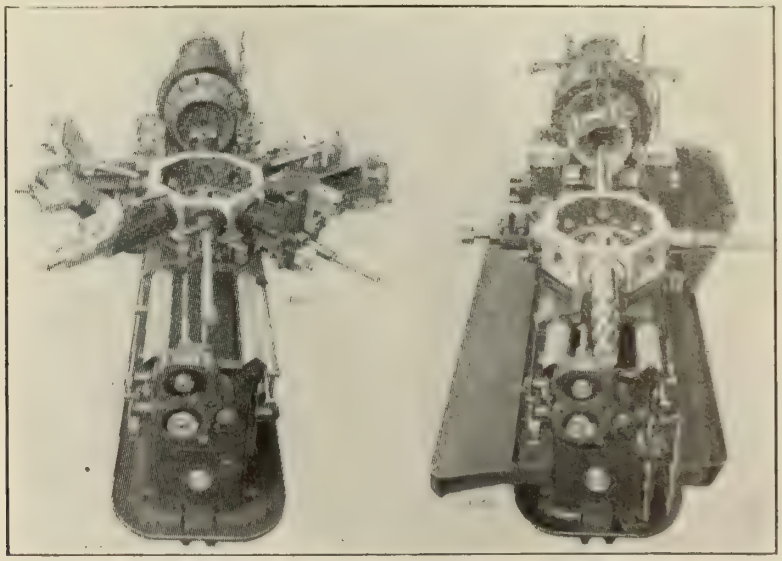

Fig. 1.—Left: automatic turret lathe set up for machining flywheel shown in Fig. 2. Fig. 3—Right: set-up of machine when working on differential carriers, shown in Fig. 5.

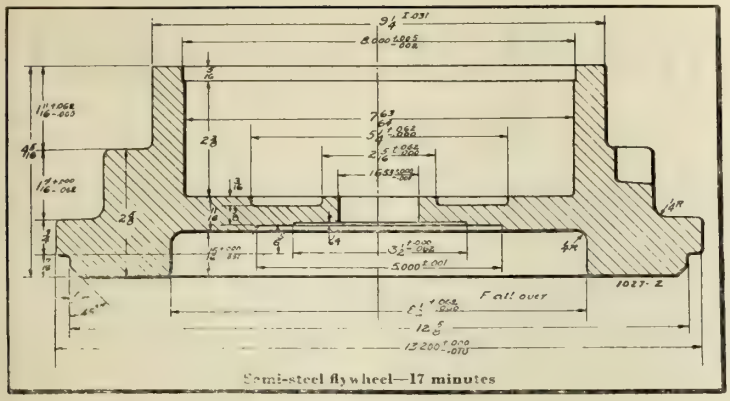

Fig. 6.—Semi-steel flywheel finished all over in 17 minutes.

is illustrated in Fig. 3, which shows the machine set-up for tooling the malleable iron differential carrier, a dimensional sketch of which is shown in Fig. 5. It was necessary to design a special chucking fixture to facilitate the proper handling and holding of this particular piece. Where the work is of an irregular shape, and production is sufficient to warrant the construction of single purpose chucking devices the advantages derived more than repay for the initial cost of the special fixture. The time required to place the work in the chuck is then reduced to a minimum and assures a higher degree of interchangeability, especially when some of the surfaces are not machined.

The sequence of operations on this differential carrier is as follows: After the work is located in the special fixture the several bores, A, B, C, D, and E are roughened with the cutters held in the bar located in the first face of turret; simultaneously the faces F and G are roughened with the tools held in the front rest. The finish boring and facing of the respective surfaces just mentioned is accomplished by the boring tools in the bar held in the third turret position. The final facing is accomplished at the same time by the tools in the rear slide rest. The fifth turret face carries the triplex reamer for finishing the three bores A, B and D. The thread C is tapped with the collapsible tap carried on the seventh face of turret. In this case the alternate faces of the turret are not used.

The possibilities of the heavy duty automatic lathe is indicated by the sketch Fig. 6. This is a semi-steel flywheel and is finished all over, in some places with high and low tolerances of .001 and less. The extreme outside diameter is 13.2 in. These parts are finished in 17 minutes, floor to floor.

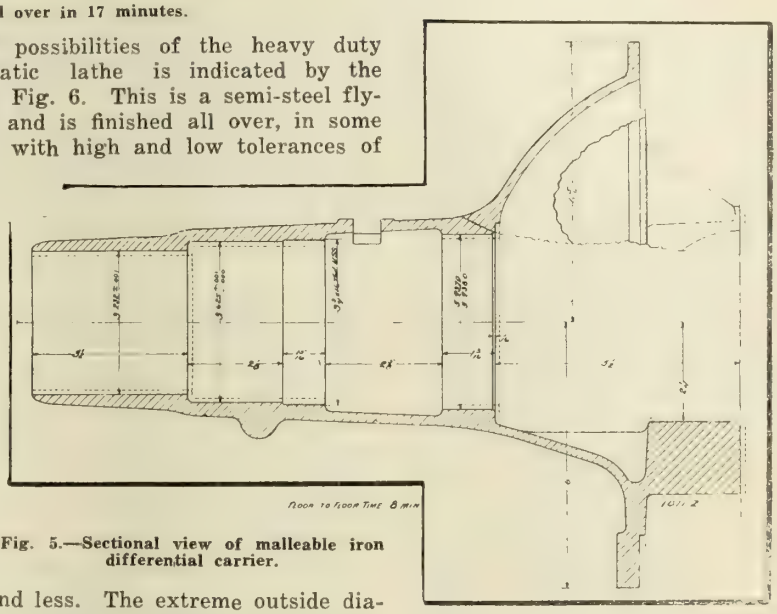

Fig. 5.—Sectional view of malleable iron differential carrier.

Feed Control

The various feeds are controlled by four independent sets of change gears which can be used for any face of the turret or for feed of cross slide in either direction. When the fine feeds are used, the length of cut is regulated by a timer dial which trips the feed at the completion of a predetermined number of spindle revolutions. Independent trip blocks are provided on each face of the turret so that each tool mounted on any face is entirely independent of the others as regards the point at which the forward quick traverse is disengaged and the feed engaged.

As the handling of the work is generally considered one of the chief unproductive factors in the manufacturing problem, the reduction of the necessary idle time between machining periods is important. For ordinary work the machine used on these operations is equipped with an air operated chuck controlled by double acting air cylinder. The mechanism provides for either internal or external chucking, and when the character of the work necessitates a light grip, the air pressure on the chuck jaws is reduced by an automatically controlled air regulated valve. The air cylinder on these machines is mounted on the spindle between the bearings, thus avoiding the overhang necessary when the cylinder is located at the rear.

Shafting must be supported at regular intervals by hangers in exact line. The least inaccuracy of alignment of hanger bearings demands that the shaft be bent by that amount continuously as it revolves, and this bending strain eats up power, racks the hangers, and tends to throw off the belts.

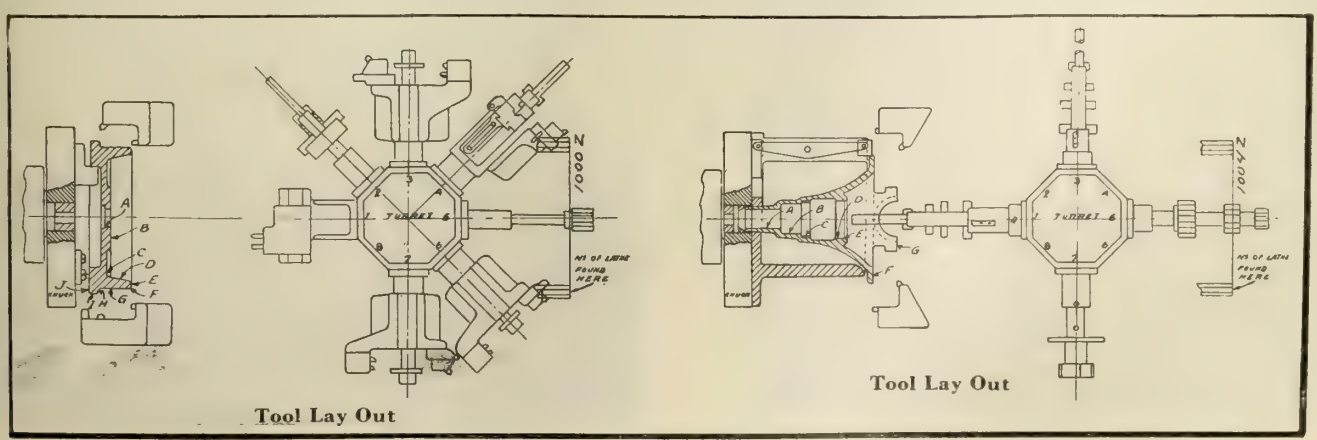

Fig. 4.—Left: tool layout for automobile flywheel shown in Fig. 2. Right: arrangement of tools when machining differential carrier shown in Fig. 5.

News From the Welding Field

Result of Several Tests Made on Welded Cylinders

Method of Making Seamless Pipe—Process of Welding Girth Seams—Practice Followed in Testing the Welds—Results of Observations—Determining the Factor of Safety

By PROF. E. A. FESSENDEN and S. J. BRADFORD

WITH A view of determining the most satisfactory method of welding cylinders for handling anhydrous ammonia a number of tests were recently made at the request of a large machinery manufacturer. The cylinders tested involved the following four types of construction: Flange steel shell, acetylene-welded longitudinal seam, concave heads forge welded to shell; seamless-pipe shell, convex heads acetylene welded to shell; seamless-pipe shell, concave heads forge welded to shell; flange-steel shell, acetylene-welded longitudinal seam, convex head, acetylene-welded to shell. All of the dished cylinder heads were hot pressed from flat discs in a large press on flanging machine.

Methods Used in Making Welds

In making the forge-welded heads the shell and head were heated to the welding heat in an ordinary forge fire and the welds were made by hand hammers and sledges. Fig. 1 shows a construction of one of these forge-welded heads. The following description of the method of making a cylinder of seamless pipe will indicate the methods used for all the acetylene-welded cylinders.

A piece of seamless pipe of the required length to make the shell is cut off by an acetylene torch. The ends of this shell piece are not scarfed, the heads being welded directly to the ends as they are left by the cutting torch. The head is made of flange steel pressed into the dished shape, convex outward, commonly used for cylindrical vessels made to withstand internal pressure. The edge of the flange of the head is turned so as to make a square face and then the outer corner is beveled off to form a scarf. The shell and the head are then placed close together but not touching, the distance between the end of the shell as left by the cutting torch and the nearest edge of the scarf on the head being about ⅛ in. Fig. 2 is a detail of the method of scarfing for making the joint and Fig. 3 shows a head in the process of welding.

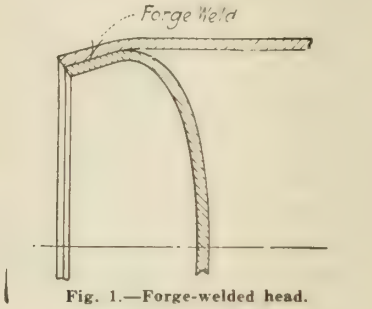

Fig. 1.—Forge-welded head.

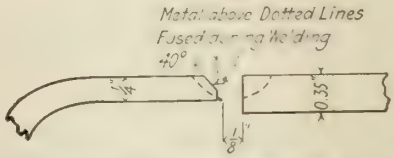

Fig. 2.—Scarfing method for making the joint.

When the torch is applied the metal of the shell and the head are first heated until they melt into a viscous fluid which flows down and closes up the gap between the two edges. Most of this material is taken from the shell, so that this melting-down process is practically equivalent to scarfing the edge previously left by the cutting torch. The metal from the welding wire is introduced not by melting it off the end of the wire and dropping it into the crevice between the parts to be welded as in a soldering operation, but by stirring the end of the welding wire in a little pool of molten material formed from the metal of the shell and head. Welds made in this manner are often called "ripple welds." Only very rarely was the hottest part of the torch flame allowed to play upon the welding wire, material from the wire being almost invariably introduced into the weld by the puddling process just outlined.

For longitudinal seams the welding operation was carried on in the same manner as that described for girth seams, the process being as follows: The plate used to form the cylindrical shell is rolled into shape so that the edges of the longitudinal joint nearly touch, the shell being laid longitudinally with the joint uppermost. The seam is then started at one end and welded for a distance of about 2 in. For the remainder of the seam the edges are spread apart and held in position by a jack. The amount of spreading is about ½ in. to ¾ in. per ft. length of seam and thin shells are spread the most. As the welding progresses toward the end where the jack is placed, the strain on the edges is gradually reduced so as to allow the edges to be welded to approach each other. This device is used to eliminate as far as possible temperature stresses due to a high temperature of the welded seam.

Method of Conducting Tests

The cylinder under test was blocked up on a light truck and filled with water through openings left for the purpose. The diameter was then carefully measured at five points equally spaced along the length of the cylinder. In the cylin-

Extract of a paper presented at a recent meeting of the American Society of Mechanical Engineers.

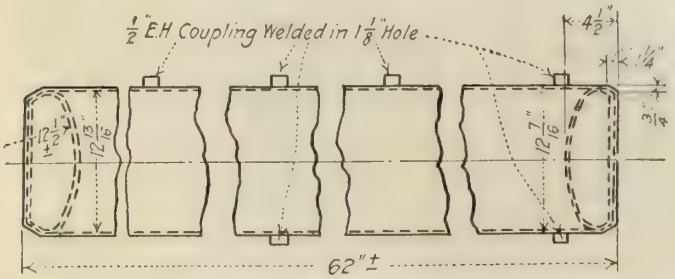

Fig. 4.—Construction of cylinder, No. 1.

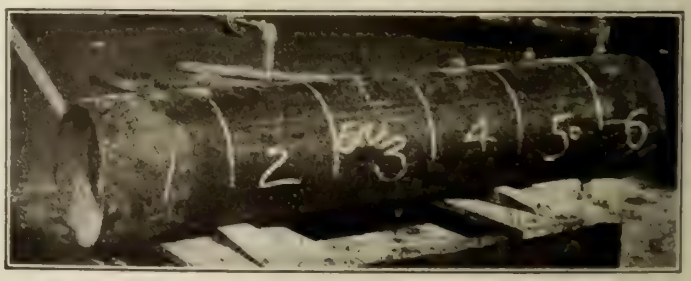

Fig. 5.—Cylinder No. 1, ready for testing.

ders made of seamless pipe these diameters were measured only horizontally as the cylinder lay in the testing rack, but in the cylinders rolled out of flange steel vertical diameters were also measured at all the five points where the supporting blocking did not interfere with the use of calipers. Careful measurements were also made to determine the contour of each cylinder head.

The cylinder was then connected to a hand-operated hydraulic-testing pump, with a new and calibrated hydraulic-pressure gauge in the connecting pipe line. The pressure was then gradually increased, stopping occasionally to observe carefully the condition of the cylinder and to repeat the measurements indicated above whenever it seemed desirable to record changes in the shape of the cylinder. This was continued until the cylinder failed to such an extent that the defects which developed caused leaks which made it impossible to operate the pump rapidly enough to cause further increase in the pressure.

Test Results on Cylinder No. 1

The construction of cylinder No. 1 is shown in Fig. 4. The shell was made of flange steel, ¼ in. thick, with the longitudinal seam acetylene welded. The heads were pressed from ¼-in. flange-steel plate to a dished shape, and with a straight cylindrical flange about 2½ in. long. The heads were inserted into the end of the shell with the convex side inward and the edge of the flange of the head forge welded to the shell, the depth of the weld being from 1 in. to 1½ in. in the case of this cylinder. The welded ends were then crimped over to reinforce the weld as shown previously in Fig. 1. The cylinder set up for testing is shown in Fig. 5. The outside diameters, measured before testing on the lines between the numbered sections, were as follows:

Between sections	1-2	2-3	3-4	4-5	5-6
Horizontal diameter, in.	12.17	12.28	12.34	12.34	12.28
Vertical diameter, in.	.....	12.41	12.38	.....	12.44

The following observations were made during the test at the pressure indicated: 500 lb. per sq. in. The concave head of section 1 began to reverse curvature, becoming completely convex shortly afterward. 700 lb. per sq. in. The concave head of section 6 began to reverse curvature, and very rapidly became completely convex. 950 lb. per sq. in. Leakage began through forge weld at head of section 1. 1350 lb. per sq. in. Forge weld at head of section 6 began to leak slightly. 1450 lb. per sq. in. Very bad leak through weld at head of section 6. Complete failure.

Fig. 6 shows the head of section 6 after complete failure had occurred at 1450 lb. per sq. in. internal pressure. The defective spot in the forge weld which caused final failure is on the upper left-hand quadrant. This illustration also shows very clearly the final shape of the head after complete reversal of curvature had taken place. Accompanying the deformation of the heads the ends of the shell which were crimped over to reinforce the weld were straightened out by the bending stress on the flange of the head. As a result, after the head had completely reversed its curvature it was found that the crimpage had nearly all disappeared. This obviously introduced a circumferential tensile stress upon the weld that probably contributed to the final failure. The spreading of the crimped end can be seen by a comparison of Figs. 5 and 6 and is particularly noticeable along the upper side of the shell.

During the test, measurements were taken to give the contours of the heads in order to show their progressive deformation under increasing pressures. These readings were later plotted.

The factor of safety may be considered to be any one of a number of values, depending upon what is considered to be the point of failure of the cylinder. The cylinders were similar to those used by the company for holding anhydrous ammonia at an internal working pressure of 185 lb. per sq. in. gauge. Using this as a basis the authors find the following factors of safety: (a) If failure is considered as occurring at the first indication of deformation of the concave heads, the factor of safety is 2.70. (b) If the vessel be considered to have failed as soon as the first leakage occurred, the factor of safety is 5.13. (c) On the basis of the maximum pressure attained in the test with complete failure of the forge weld, the factor of safety is 7.85.

At the maximum pressure attained in the test the stress in the material forming the shell was 34,400 lb. per sq. in. of cross-section, computed on the basis of the original mean diameter of the shell. If the effective thickness of the weld is considered to be the same as that of the shell material, this value is also the stress safely withstood by the acetylene-welded longitudinal seam.

(To be Continued)

If the drill splits in the web, it is either ground with improper center lip angle or the feed is altogether too heavy.

Practical Ideas From Practical Men

UNIVERSAL JIG FOR DRILLING THRUST WASHERS

By Robert Mawson

When manufacturing machine tools, washers are used to a large extent for taking the thrust on various revolving elements such as the spindle. When these machines are made in different sizes or types it is necessary to design the thrust washers also in more than one size. We recently designed and made a universal jig to take care of the problem of machining the different washers and this tool is illustrated in this article. One size of washer is shown in Fig. 1. These parts are made from punchings being produced with the outside diameter and hole within the limits specified, using commercial flat steel in sheet form. The two ⅛ in. holes are then drilled with the jig shown in Fig. 2.

The body of the tool is made of cast iron provided with machined feet at each corner so that the jig will rest squarely on the drilling machine table. At the forward end of the jig base is fastened a steel plate B machined with a vee-shaped slot made with an under cut edge of one degree for locating the washer to be drilled. On the left and right hand sides are attached two steel drill guiding plates C, these elements as well as the locating plate being held with bolts and nuts as shown. At the rear of the jig is fastened the stop plate D, a knurled headed screw being used to hold it in position.

Referring again to pieces C and D it will be noticed that these are made one inch wide and that slots are machined the same width so that the plates will slide in line and not tend to move when they are fastened down with their respective bolts. The locating plate A is secured with two bolts that are a close fit in the ⅜ inch holes drilled in the plate and therefore does not require any guiding slot in the jig body.

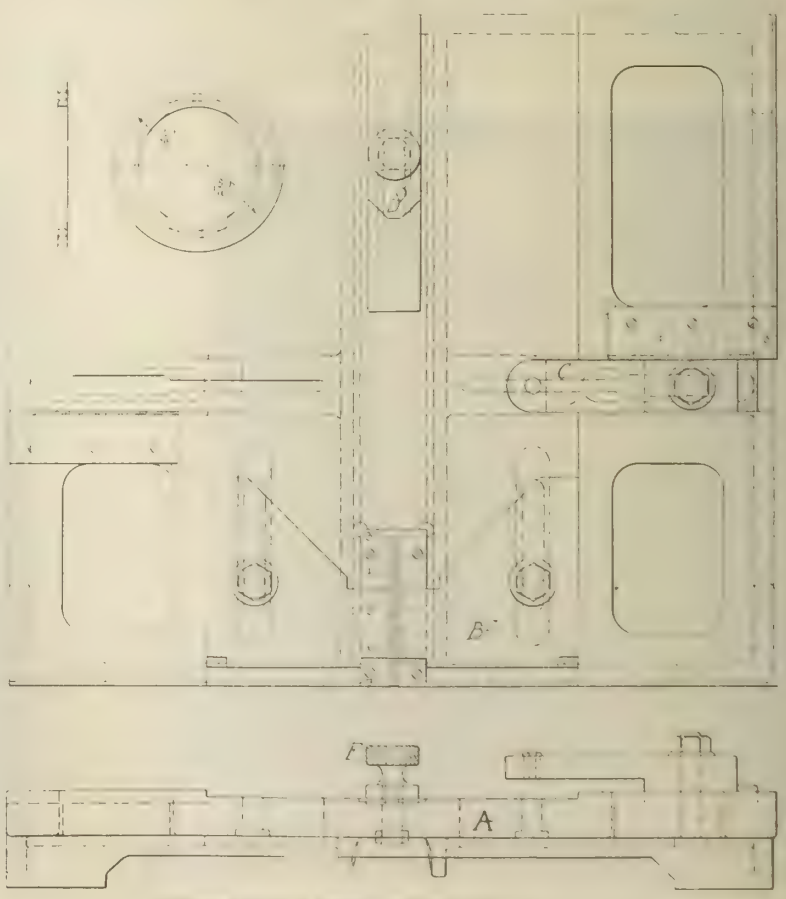
In order to provide a tool not only universal but also quick setting, three scales are fastened to the jig body, one for the locating block and one for each of the drill guiding plates. On each of these plates are machined index graduations marked with a zero. To use the jig and taking the Fig. 1 as an example, the plate A is first placed so that the zero on the edge of the plate is in line with the dimension 3¼ inches, which is the outside diameter of the washer to be drilled. It will be seen that there are three index lines, one in the center and one on each edge. The purpose of the two outer graduations is for setting the block when drilling washers of odd diameters.

For such parts the washer is first accurately placed and then a line marked on the face of the base of the jig, and a number stamped on, this being the part number of the element in question; this setting is then used for all subsequent drilling operations on this part. It will be observed that the holes to be drilled in the piece Fig. 1 are 2⅝ in. apart and to obtain this distance for the drilling plates the index zero line on detail C is placed at 1-5/16 in. which is half of the total spacing between the holes. A second graduation on the lower side of the plate is used for setting when drilling odd spaced holes or those which are not in even 1/32 of an inch, the scales being graduated for this reading. The manner in which this lower scale is used is similar to that noted for the locating block and need not be repeated. After the washer has been correctly located as described the plate D is brought up against the rear end and after being fastened with the screw, the plate holds the washer firmly in position for the drilling operation.

This jig can be used for drilling washers from 3 to 7 inches inclusive, a smaller tool of similar type being employed for washers up to 3 inches diameter. A quick acting feature of the tool is the knurled screw E which secures the locking plate D, so that after the plates B and C have been once correctly set and fastened down, all one size of washers can be drilled quickly and interchangeably, it being not necessary to loosen the knurled head screw E, slide back the plate D, and either put in a washer ready for drilling or remove the one already machined. After the washers have been drilled with this jig the oil grooves are formed in a standard milling machine for this work. The sides are next ground within the limits specified, this work being performed on a vertical grinder, the washers being held on magnetic chuck.

It might be added that this tool is simple in construction as may be seen from the illustration but produces parts quickly and absolutely inter-changeable and during the work the man can at all times be assured that the correct spacing is being obtained as a simple check on the graduated scale will furnish this information.

If a twist drill chips on the edge it invariably indicates that the lip clearance is too great and fails to support the cutting edge.



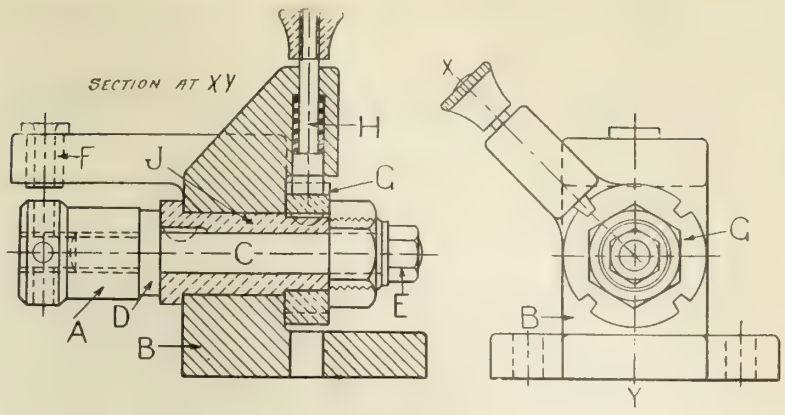
Universal jig for drilling thrust washers.

INDEXING DRILL JIG

By Hubert Bentley

The accompanying drawing, shows a simple but effective indexing drill jig, used for facilitating the quick and accurate drilling of four equally spaced holes in cast iron bosses or centres, ready for the insertion of the handles. The cast iron boss is shown in position ready for drilling at A. It is the type used with two, three or four handles for the friction feed engagement in various machine tools. Prior to these holes being drilled, the boss is bored and tapped out a fine thread to fit the shaft which carries the friction disc and is also turned up on the outside. The jig body B is in one piece of cast iron with a suitable foot and lugs for securing to the drilling machine table. The boss to be drilled is mounted on the threaded end of the spindle C, which is keyed to a bush J, fitting in the main casting. The boss is tightened against the collar D which in turn is drawn up tight by the small hexagon nut E at the other end of the spindle. Drill bush F is carried in the projecting arm an guides the drill. It should be noticed that the part of the boss to be drilled is quite clear of the spindle end so that damage does not occur when the drill comes through.

A division plate G with four grooves cut across, into which a spring operated steel plunger H engages, enables accurate spacing to be accomplished. On the completion of the first hole, the plunger is withdrawn by hand and the work turned round until the next groove engages the plunger. This operation is continued until all the holes have been drilled and tapped. To suit the different bores of the bosses for various sizes of machines, spindles with screwed ends of differing diameters were required and interchanged when necessary. It will be understood that the jig is applicable to any number of equally spaced holes being drilled according to the number of grooves cut in the division plate.



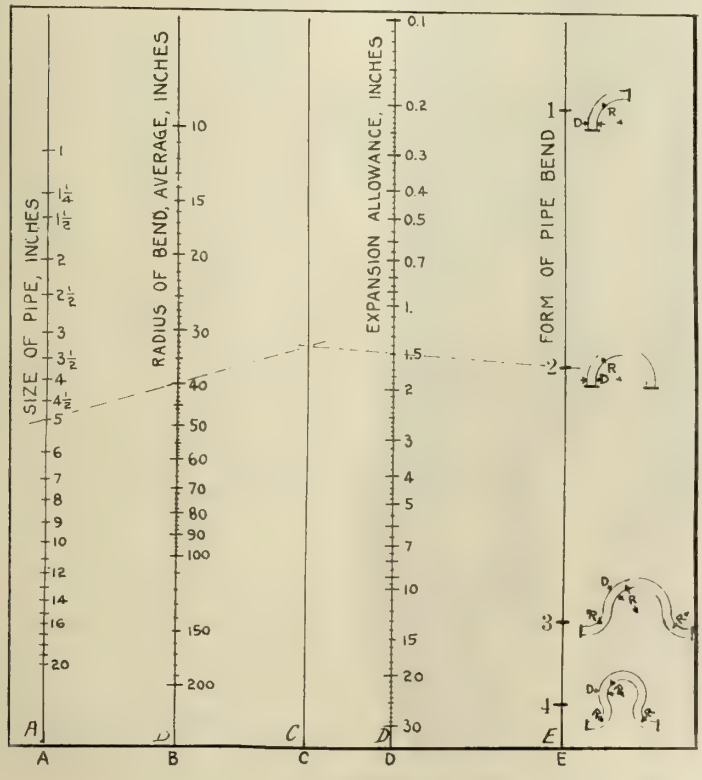
A USEFUL PIPE BENDING CHART

By W. F. Schaphorst

Here is a chart that will be found valuable and convenient for determining the average radius of bend that should be given to common forms of pipe bends, numbers 1, 2, 3, and 4, as shown at the right, column E. Or, knowing the radius of bend, the size of pipe, and the form of bend, column D gives the expansion allowance of that bend.

For example a five inch pipe was made to a radius of 40 in., the bend being a common U-bend as shown by No. 2 in column E. What expansion may be allowed? The dotted line drawn across this chart shows how it is used. Run a straight line through the 5 column A and the 40 column B and locate the intersection with column C. Then from that point of intersection run over to the mark in column E opposite the figure 2 and the intersection through column D gives the answer as 15 inches expansion allowance.

Similarly if the expansion allowance, the form of bend, and the size of pipe are known, the average radius to which the bend should be made may be determined in the same way. In other words knowing any three of the four factors given in columns A, B, D, and E the fourth or unknown factor is easily determined by following the method as explained above. This chart is based upon the following much used and well-known rules: For bend No. 1—Square the average radius of bend in inches and multiply by 0.0026 and then divide by the outside diameter of the pipe in inches. Bend No. 2.—Same as No. 1 but use 0.0052 instead of 0.0026. Bend No. 3—Same as No. 1 but use 0.0104. Bend No. 4.—Same as No. 1 but use 0.013. In the chart all of these operations are already performed—the radii are squared, exact outside pipe diameters are employed, and the proper factors are used.



Pipe bending chart.

'LECTROMELT CALCULATOR

The Pittsburgh Electric Furnace Corporation have just developed a handy calculator made of celluloid for figuring the amount of ferro-alloy required for different alloys and various metal mixtures to allow any given percentage of alloy, and allow any ordinary percentage of loss in the absorption of an alloy. This device is intended for the aid of the furnace superintendent and melter in the foundry and metallurgical industry generally, and on account of the rapidity and accuracy with which the calculations are made, will serve a very useful purpose throughout the steel and metal field. The device is of circular form, 7 inches in diameter and made in three pieces pivoted in the centre. Six graduated scales provide for the direct reading of the various elements used in the calculations. The price of this device is $5.00.

New Things in Shop Equipment

SELF-FITTING KEYS

To facilitate the rapid fitting of keys a special type, capable of making its own fit in the keyway by shaving the sides of the latter as the key is driven in, has recently been placed on the market. Owing to the fact that the section of the keyway in the shaft and that in the hub are seldom in accurate alignment a certain amount of fitting is usually necessary. In making this special key a tough chisel key is used for the key, which is ground to a size slightly larger than the nominal keyway width. One end of the key is provided with a cutting edge and chip recess. Ahead of the recess is a pilot a little smaller than the keyway so that it fits the latter and guides the key. When installing the key the pilot is entered with the cutting edge on the side and driven home with a hammer or sledge, depending on the size of the key. On the smaller sizes the cutting edge is placed on the one side only but on the larger sizes double cutting edges are used. Special keys with three cutting edges may be obtained if desired. These keys are made in a wide range of sizes and are made by Smith and Serrell, Newark, N. J.

HEAVY-DUTY GEARED-HEAD

A lathe particularly adapted to heavy service has recently been placed on the market. It is stated that these machines are capable of transmitting double the power ordinarily possible with lathes of the same size. The 16-in. lathe will transmit 9.2 h. p. with a belt pull of 65 lb. per sq. in. The direct-connected motor-driven lathes can be fitted with either chain or belt drive. The belt drive is direct from the countershaft to a constant-speed pulley. A feature of the machine is a disc clutch fitted with a brake which is incorporated in the drive so that the spindle is disconnected from the gearing when the machine is stopped. This does away with the flywheel effect of large rotating gears attached to the spindle. This action is of special advantage when centering irregular work in the chuck, Twelve spindle speeds can be obtained by means of three handles on the front of the head. In the 16-in. machine the speeds range from 13.5 to 400 r. p. m. in geometric progression. The lathe can machine work at its maximum swing at a cut speed of 55½ ft. per min. It is claimed that the complete range of speed changes can be made in 12 seconds. These lathes are made by the Cincinnati Lathe and Tool Co., Cincinnati, Ohio.

ACME OIL DRIP PAN

A drip pan especially made for use on hangers for catching oil from bearing boxes, has been placed on the market recently. These pans are made in three sizes, all of which are 2 in. deep, and can be quickly installed or removed without disturbing the hanger or bearing. They are made by the Akron Sheet Metal Co., Akron, Ohio.

IMPROVED WIZARD CHUCK

This drill press chuck consists of only two main parts, a driving body with a Morse taper shank to fit the drill press spindle and a slotted collar to hold the collet up in the driving body. This collar is straight and uniform in shape and hardened all over. These improvements are said to increase the resistance to hard usages and make the chuck much easier to handle. The bayonet locking slots in the collar that admit the driving lugs of the collet are so designed that the collet can be inserted or released with one hand, without slowing or stopping the machine. Little mechanical skill is necessary. To insert a tool the operator needs only to push the collet into the revolving chuck. The positive, automatic latch locks it instantly. Releasing is also rapid and easy. A slight pressure of the thumb and forefinger on the knurled collar of the chuck releases the collet instantly and allows it to drop into the operator's hand. These chucks are made by the McCrosky Tool Corporation, Meadville, Pa.

Wizard drill chuck showing method of locking and release.

PORTABLE DISC SANDER

A 9-inch motor-driven disc sander suited to general work has been placed on the market recently. The machine is fitted with garnet paper discs for sanding wood and grinding brass and aluminum, while emery cloth is used for iron and steel. The machine is self-contained, the motor being directly mounted on the disc shaft; being set on a pedestal the unit is easily portable.

The motor is of 1-6 h.p. operating at 1,725 r.p.m. A tumbler switch is provided on the end of the motor. The table is located 38 in. from the floor and is 5¼ x 10 in. in size. Provision is made for tilting it to an angle of 45 deg. down and 15 deg. up. A thumb screw serves to tighten the table firmly at any angle, a graduated plate providing an accurate means of setting. The head is so mounted as to be turned to any desired position on the pedestal. The machine is made by the Syracuse Sander Manufacturing Co., Syracuse, N. Y.

TELESCOPING TIERING MACHINE

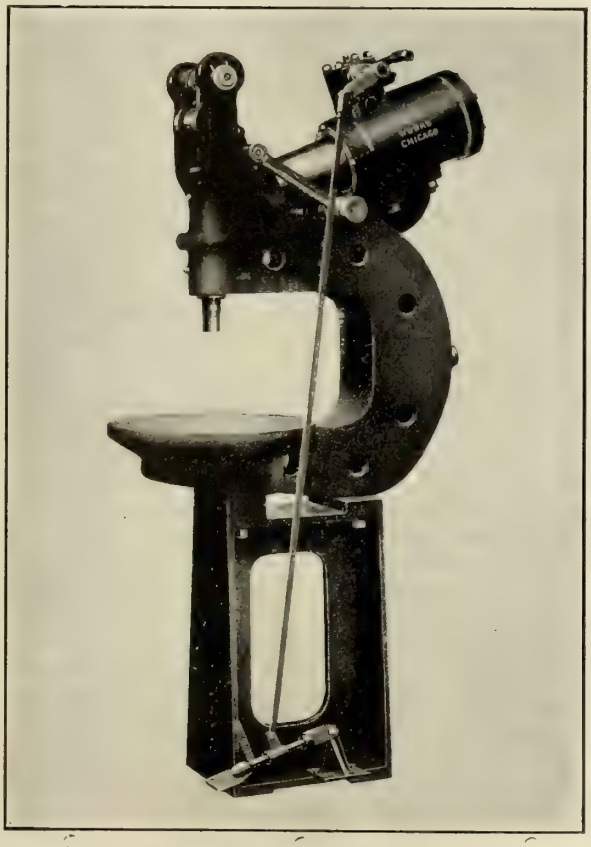
A portable tiering machine in which one section of the frame telescopes into the other, providing a lift nearly twice as high as its normal height, has recently been developed and placed on the market. Both hand-operated and electric driven machines are constructed, the heavy duty type being operated from a power line while the lighter sizes may be operated from an ordinary lighting circuit. The machine is mounted on three roller casters for moving about the plant, but when located for lifting or tiering purposes the steering wheel is raised, allowing the truck to rest on two fixed legs and prevent the machine from moving. When using the machine for raising material above the minimum height the platform is raised to the top of the inner frame and then the latter, together with the platform continues to move upward to the desired height. The reverse action takes place when lowering the platform. The platform is automatically held in position at whatever point it is stopped. Protective devices are provided on the power-driven machines for automatically stopping at the top and bottom limits of travel. These machines are manufactured by the Economy Engineering Co. of Chicago, Ill.

UNIVERSAL INCLINOMETER

A device intended for direct reading and checking of angles has recently been offered to the trade. This instrument consists of an aluminum housing carrying a graduated dial and mounted on a semi-steel base. Pivoted in the centre of the dial is a vernier pendulum that always hangs in a vertical position. A small brake is employed to steady the pendulum after the setting has been made. It is especially adapted to tool room service and for structural and erection work. The graduations provide for reading to every 5 min., but the device can be fitted for one min. reading if desired. The instrument is plumb when the zero on the pendulum coincides with the zero on the dial. As the dial is graduated on the entire circle a reading may be obtained when in any position. The base is ribbed and may be fitted directly to the work being measured. The base is made in lengths of 7, 18 and 24 in. For similar angles the reading will always be the same irrespective of the operator using the instrument. These tools are made by the Stevens-Prentice Mfg. Co., Milwaukee, Wis.

TOGGLE AND LEVER PRESS

A pneumatically operated general utility press has recently been offered to the trade. The press can be equipped with various forms of platens or work-holding fixtures, so as to make it adaptable to such work as straightening, bending, forcing, marking, and many similar operations. The machine is built in a number of sizes ranging in capacity from 15 to 200 tons. The press is self-contained and is portable in every sense. It only requires a small floor space. An adjustable screw is used for locating the vertical position of the die. Adjustable toggle mechanism allows of regulating the length of stroke. The piston imparts to the die a gradually decreasing speed and an increasing pressure for each unit of piston and travel during the first part of the stroke. The last portion of the stroke is made at a uniform pressure. In bending and straightening operations it is possible to throttle the air supply so as to apply just sufficient pressure to deflect the work the desired amount. If the die travel is stopped by contact with the work at any point within the uniform pressure stroke the pressure on the die is a known predetermined amount in proportion to the pressure in the air line. When used for marking, embossing, forging, etc., the pressure can be regulated by means of the valve and maintained at the pressure while that particular job is being performed. These presses are made by the Hanna Engineering Works, Chicago, Ill.



Pneumatic toggle and lever press.

AUTOMATIC DIE SINKING MACHINE

A new die sinking machine that is automatic in action has recently been placed on the market. It is designed for such work as forming, stamping, and forming dies, core boxes and pattern work, requiring impressions up to 36 x 20 in., and 8 in. deep. A master form is used for the control of the cutter movement and this may be made of plaster, cement or wood. Only a light pressure is necessary on the tracer point. The machine is constructed to combine tremendous cutting power with great accuracy in following and reproducing any design of pattern. The work is practically finished when it leaves the machine. It is possible to adjust the machine to make allowance for stock thickness. Automatic feeds both horizontal and vertical are provided and on the horizontal travel, quick return is provided for.

Any shape of contour may be obtained from the pattern. The table has a working surface 53 x 22 in., horizontal travel of 36 in., and change gears provide for speed range of from 1½ to 12 in. per min. The vertical slide has a travel of 20 in., with a feed of .10 in. to .83 in. per stroke, which may be increased if desired. A counterbalance is provided for this slide. The spindle is mounted on the vertical slide and has a horizontal movement, in and out, of 8 in. Its movement is controlled electrically. For working an outline on one plane, a special attachment is provided for contouring and profiling; with this device in use the in and out movement is made inoperative.

There is one slow and one high speed spindle. The spindle drive is by a separate motor direct connected with the lower cone pulley shaft on the rear side of the column. The upper cone pulley shaft carries the spindle driving pulley. Two spindle driving pulleys are provided, 4 and 6 in. in diameter, and interchangeable. The slow speed spindle pulley with the back gears are mounted as a unit on the spindle head. The high speed spindle is driven through a grooved pulley from the slow speed spindle pulley shaft. The ratio of back gearing is 3,-724 to 1. Eight changes of speed are provided, four with back gear ranging from 80 to 216 r. p. m., and four with open belt from 298 to 808 r. p. m. Extra high speed can be provided up to 2,424 r. p. m. The machine requires a floor space of 9 ft. x 8 ft.; the height is 6 ft. 8 in. It is manufactured by the Keller Mechanical Engraving Co., Brooklyn, N. Y.

PULLEY GRINDING MACHINE

A machine for grinding the faces and edges of pulleys has been placed on the market recently. The machine is fitted with a 14-in. dia. wheel mounted in a steel chuck. The wheel spindle operates on ball bearings at a speed of 1,500 r. p. m. The work carrier accommodates pulleys from 2 to 18 in. in diameter up to 6 in. face, the work being supported on a pintle positively driven through speed change gears. The work table has screw-operated movement in three planes, and an auxiliary rapid travel to and from the wheel actuated by a hand lever. It is possible to grind pulleys with crown, flat or concave faces by adjusting the work to the desired position. Instead of the usual conical surfaces the face has the form of a true ellipsoid curve. The work is completed in one operation, leaving a semi-polished surface. An attachment is supplied with the machine that may be used for mounting the work when grinding the edges. Guards are part of the usual equipment to provide adequate safety to the operator. Floor space required is 3 ft. 6 in. by 4 ft. 6 in. The machine is made by the Diamond Machine Co.,

It is desirable in the case of long shaft drives to reduce and steady the torque, or twisting, stresses by putting fly wheel pulleys at intervals along the shaft near the drive end. This treatment adds to the smoothness of running of the shaft, the belts and the machine which it drives.

A hanger is no stronger or better than its foundation in securing perfect operation of the shafting and its drives.

Steady Improvement

REPORTS that there has been no falling off in the demand for structural steel are taken to indicate that industry has been more steadily employed in this department than is commonly supposed. Nine months' record shows that steel imports alone are practically double those of last year, and that the demand continues in spite of shipment delays arising out of recent strikes.

Steel warehouses report that, while small orders are not so plentiful, bulk business continues to show fair tonnages. There is, generally, an improvement over last year, and although prices have steadily advanced, they have not brought out any evidence of conservative buying. This is said to indicate an optimistic outlook and confidence that the general movement is in the right direction.

Students of conditions in Canada and United States, and of their relative significance, declare that there should be some reflection, on this side, of the great activity in evidence on the other side. Railways have been a great factor in the improved demand for steel in the United States, while here there has been very little buying either by the C.P.R. or National lines. It is claimed that they have all the material necessary in maintaining track and rolling stock efficiency. Even though a bumper wheat crop looms in the West, it is claimed that Canadian roads are well equipped to handle it.

In spite of the absence of the railroads as a large buying factor, iron and steel business has developed steadily. Much of the improvement is undoubtedly due to general building activity. Government statistics show that in 56 cities during August, permits had a value of $16,970,125, as compared with $14,275,026 in the preceding month, an increase of 18.9 per cent. The total, moreover, was $6,984,531, or practically 70 per cent. higher than for August of last year, the 56 cities having issued permits to the value of $9,985,594 during that month.

Do It Automatically

MODERN industry owes much to automatic machinery. High production records may, as a general rule, be traced to the employment of self-acting equipment. Munition manufacturers, during the war, demonstrated the efficiency of automatic machine tools. In fact, it may be said that every phase of the world struggle, from the workshop to the firing line, brought many devices into play in which the necessity for manual operation was reduced to a nicety. Time, labor, and money had to be conserved. Intensive team work was necessary, and mechanical means to that end were not overlooked.

Electricity, compressed air and automatic mechanisms constitute a mighty trio in the world of industrial effort. Human ingenuity has employed them, in almost innumerable ways, in the elimination of human frailty or in co-operation with human effort. The accuracy that is essential in finished products of iron and steel is almost entirely due to the work of the automatic machine. Fine adjustments and interchangeability, whereby several different operations may be performed simultaneously, or in succession, upon the same machine, represent, it has been said, "an intelligence that is human and a regularity and precision that verges on the superhuman."

Automatics have been a quickening influence in the competition that is "the life of trade." They have enabled men to do things better, to solve problems of time, and to produce, rapidly and efficiently, goods required for world markets. Not only in the machine tool industry has the automatic been seen to peculiar advantage. The weaving, spinning and knitting industries owe much of their development to this equipment. Canada, within comparatively recent years, has seen remarkable growth in the production of knitted goods, and automatics for this purpose are adapted to a wide range of purpose. Railroads are using automatic railway signal systems in introducing a maximum of safety into their operations

There is probably no department of mechanics in which engineering ingenuity has found expression in so varied and interesting form, and industry generally is receiving immeasurable benefits.

Adequate Outlet Wanted

ADDRESSING a gathering of business paper editors during their annual convention in New York, Julius Barnes, President United States Chamber of Commerce, stressed the fact that not until there was adequate passage to the sea for the products of the West, would agriculture function properly as a stable foundation for industrial and commercial activity.

With trunk railway lines unable to handle, eastward to New York, all of the business that was offered, with the Erie Canal hardly a factor, and with the Canadian water route from Buffalo to Montreal equipped with facilities of forty years ago, a condition was set up which advanced freight rates and, to that extent, prevented proper return to the farmer. Large freighters on the upper lakes earn comfortable dividends on a basis of two cents per bushel. If the same service existed east of Buffalo and on to Montreal it would add 10 to 15 cents a bushel to products west of Duluth, Chicago and Fort William. This would eventually have its effect upon industry generally, while the markets of the world would be available without handicap.

Steel Markets Showing Easier Price Tendencies

Due Largely to Settlement of Strikes—Industry Not Slowing Up —No Reductions in Steel Quotations—Competition Growing in Pig Iron—Demand for Boiler Tubes—Machinery Prices May Advance

THREE DOLLAR DROP IN DOMESTIC PIG

ALTHOUGH there have been no declines in steel prices, some readjustment is appearing in coke and pig iron. Canadian furnaces announce a reduction of $3.00 bringing the price per ton to $36.30, while Pittsburgh reports a softening process that does not appear to be sufficient to produce a market.

It would almost appear that buyers had anticipated more of a shortage in deliveries than has developed, but there is no indication that the easier undertone to the market is caused by decrease in general industrial activity. Seasonal influence will undoubtedly have its effect, and while it may develop that there has been a fair amount of work done, it is more notable that progress has been made in spite of strikes and other problems. The easier price tendency may be attributed almost entirely to cessation of labor troubles.

Steel ingot production is back to the rate of last June, or on a basis of about thirty-seven million tons a year. The August production had dropped to a basis of twenty-five millions, while September had a corresponding increase, showing a thirty-three million ton average at the close. At the present rate of going, according to advices from American centres, a shortage in production need not justify consumers stocking in anticipation.

While the general tone of the steel market is easier, no reductions have been made. Merchant bars have been quoted at $2.00 mill, Pittsburgh, but it is said some are offered at $1.95. The Hamilton price rules at $2.70, with the Montreal and Toronto warehouse range from $3.15 to $3.25. There has been a good demand recently for boiler tubes. This is a seasonal feature, and prices show a slight advance, about 5 per cent.

Congestion at American centres of production is undoubtedly a factor in maintenance of prices. Shipments are much below production, but it is reported that steel mills are not accumulating anything like the volume they had at the high point of 1920, when three million tons of finished steel were piled up. At the present time there is not one-tenth as much, and mills are reluctant to go further, as buyers may not want the material if late in delivery. The unfilled obligations of the Steel Corporation, at the end of September, amounted to 6,691,607 tons.

Montreal reports that no price changes are anticipated, and that they will remain steady until the close of navigation. The limit of the upward movement has been reached, and revisions, if any, should be in a downward direction. The situation as regards galvanized and black sheets has become a little easier owing to slight falling off in demand and larger supplies from British mills. There is good demand for boiler tubes and the market is adequately supplied.

Some machine tools and mill equipment are moving, but the demand spasmodic. There is some indication that prices may move higher, as it is a question whether machinery reproduction could be carried on at present figures. Should the movement acquire strength, it will, it is said, tend to eliminate the "business-at-any-price" element that makes its appearance under conditions that have existed for the past year.

Toronto

October 18

WITHOUT feature, but with general demand shaping well for a favorable month, the market appears to be proceeding along lines that generally mark the year-end season. The inventory period is in sight, and with prices at their present level, buying, it is predicted, may show a hand-to-mouth tendency. There are not likely to be any price recessions until well into the new year. An analysis of the situation establishes that fact. Steel men say that storage and extra cost of handling, while products are piling up, during shortage of cars, would be sufficient in themselves to discourage expectation of reduction, to say nothing of labor and coal costs.

Import steel tonnages, which doubled during September over August, show a slight falling off this month, but this was expected as business in this department has shown a remarkable record largely on seasonal operations. The railways have not appeared in this market to any extent, apart from comparatively light tonnages of rails, while on the other side, a slight advantage in the market, preceding Oct. 1, brought out orders for a million tons. The taking by the New York Central, one hundred thousands tons, is about the amount turned out by the Algoma Steel Co. this year. The coming year should see marked improvement in railway activity.

Pig Iron.—A reduction of $3 per ton on domestic iron has been announced as effective Oct. 13. This brings the Toronto price to $36.30, and may be regarded as representing some easing in conditions under which Canadian furnaces were operating. Buffalo producers also reflected improvement in their prices and, as a result, a serious competitive factor was developing. Domestic furnaces may be expected to improve their position gradually. There are those who look for $25 iron "before snow flies," but furnace men reply that if the weather is at all sympathetic with difficulties surrounding pig production, it will be a green Christmas at least. Reports from American centres indicate a softening with little business offering. Buffalo is quoting 2.25 and 2.75 silicon at $33 and malleable at $32.

Iron and Steel.—That stage has been reached where advances seem out of the question, and declines impossible. There has been a range from $3.25 to $3.40 in bars, but the latter figure never became a fixture. Quotations depended upon the buyer and terms of purchase, although some dealers declare that a boost in price of 50 cents during the past four months has been about all the traffic would bear. By these people, $3 40 is considered an absolutely outside figure. They are the conservatives who maintain that business is at that point where it may be made or marred by a trifle. On the other hand the market is not without those students who declare that Toronto prices have represented a proper spread as between mill and warehouse. Current prices follow:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 75

Scrap Materials.—This market is described as "quite steady, but without spectacular movement." There is not much offering in machine cast iron, or in any other grade for that matter, and at the present time much of this material is going out of the country. Copper scrap is stronger. Copper wire is quoted at $11.50; heavy copper at $12.50; crucible copper at $12 and light copper at $9, but much depends upon grading, and on handling necessary for market requirements. Dealers' average buying prices follow:

Copper, light	9 00
Copper crucible	12 00
Copper, heavy	12 50
Copper wire	11 50
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine castiron	18 00
Pipe, wrought	7 00

Non-ferrous Metals.—For what business is going in ingot metals, there is keen competition. Dealers declare that sales taxes, amounting in all to 6%, as between sellers and ultimate purchaser, has done a lot to divert big business away from middlemen, who have been considered necessary when quick deliveries are essential, or when the small buyer has to be considered. There is, practically, a double sales tax, one of 3¾ per cent. on being cleared through customs, and one of 2¼ per cent. from the dealer to the manufacturer. Large buyers, however, by buying direct, may now save the 2¼ per cent. Small foundries, however, are not in that fortunate position. Their purchases are not large, and they buy through the dealer. Much non-ferrous scrap is now going direct to the foundries, rather than through dealers, in order to save taxes and extra handling charges.

Much war material is still on the market. There are great supplies of lead with small percentages of antimony. Supplies of this bulk so large in fact that the price is below normal. The demand comes from producers of type and babbitt metals. Prevailing prices:

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	37 00
Antimony	8 50
Spelter	8 50
Antimony	8 50
Aluminum	23 00

Machine tool demand continues spasmodic. Enquiries are good, and some sales are being made, but there is no steady movement, and what is selling requires keen salesmanship. Some stiffening of prices is reported. It is doubtful if dealers could reproduce for present figures the equipment that has been sold during the past six months. Sales at any price have, therefore, become faded out, as a feature of the market. Shop supplies and mill equipment still make a fair showing.

Montreal

October 18

MARKETS during the past week have been quiet, although business on the whole has been well up to the average of the past six months. Industry is still hampered by poor deliveries on materials coming from American steel centres and this may delay progress on work scheduled for advanced operations before winter. However, the prolonged favorable weather is an assisting factor.

Discussing general conditions here, a large dealer had this to say:—

"In regard to general conditions, we might say that no price changes are anticipated. They are steady and with indications that they will continue so until the close of navigation. The opinion is generally current that the upward trend has been reached and, with a fair demand prevailing, values will remain on about the present level for some time, but any revisions should be in a downward direction.

"**Galvanized and Black Sheets.**—The situation regarding supplies in stock can be said to have become a little easier particularly in regard to galvanized sheets. Two reasons account for this, namely: a falling off in the demand and receipt of larger supplies lately from British mills, but prices on both commodities hold firm for the present.

"**Boiler tubes.**—The demand continues to keep up and stocks are quite able to take care of all supplies needed. Prices are holding steady."

Pig Iron.—There is no doubt that the supplies of Scotch and English pig iron on the market have helped save the day for foundries that were running short. Although it may be that much of this iron came in as ballast, rather than exclusive cargo, and the full amount, therefore, not large, it arrived at the psychological moment. Some export business, England to U. S. A., is being done through local houses. It is not so much competition from this source, however, as from producers of pig iron in Buffalo district that a reduction of $3 per ton on domestic iron has become effective. Whereas Ontario consumers are continuing to buy liberally, there is not much change in Eastern Canada, general foundries still being poorly occupied and manufacturers of special castings fairly well covered for their immediate needs. Prices follow:

Algoma, No. 1, car lots on tracks, nominal quotation		38 65
Summerlee, 30-ton lots, dock	35 00	
Carron, 30 ton lots	35 00	
Do., 5 ton lots, ex. warehouse	40 50	

Iron and Steel.—Merchant bars are still in strong demand, with no change in prices. The likelihood that there may be an easing in American quotations may explain a conservative tendency in buying, but in well-informed circles, it is considered unlikely that there will be any reduction until first quarter 1923. Products are piling up at production points owing to scarcity of cars, and this fact alone, it is claimed, will have a tendency to keep prices at present levels. In some quarters slightly easier prices have been reported on sheets, but this may be regarded as one of those superficial fluctuations significant of nothing. The range on black sheets, $4.60 to $4.75, and on Canada plates, $6.40 to $6.50, is a narrow one, and may be said to represent selling factors rather than basic market movement. Zinc sheets are quoted at $9.75 to $10.25. Prices follow:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 25
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	3 40
Sheets, black, No. 28	4 40
Sheets, blue, ann., No. 10	4 00
Canada plates, dull, 52 sheets	5 50
Canada Plates, all bright	7 00
Galvanized Sheets, No. 28	6 50

Non-ferrous Metals.—Markets in these lines are generally firm. Ingot metals are more active, except copper, which is rather dull and slightly easier. Tin is especially strong. Prevailing prices:

Lake Copper	17 75
Electrolytic Copper	17 50
Castings, Copper	17 25
Tin	36 50
Lead	7 50
Spelter	9 00
Antimony	6 75
Aluminum	22 00

Scrap Metals.—There is no outstanding activity in this market, although prices have been quite firm. Dealers' average buying prices follow:

Copper, light ... per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

In copper products, some stiffening of prices has appeared. Copper bars are quoted at 30-31; plain sheets, 32-36; copper sheet, 39-41; copper sheet, planished, 44-46. Deliveries of materials from mills show little improvement.

Pittsburgh

PRICES in the iron and steel industry have entered into a period of readjustment. A week ago, coke began declining sharply and pig iron is now in the act of declining, although it has gone down but little as yet. There has been practically no decline in steel prices, merely a softening in the undertone.

Occasion for readjustment is furnished by the ending of the coal strike, making production of coal, coke, pig iron and steel easier, and probably also by the existence of stocks of steel of considerable size in the hands of buyers, who anticipated more of a shortage in deliveries by the coal strike and the subsequent transportation disability than has actually occurred.

There is no definite evidence that readjustment is influenced by any unfavorable change in the general volume of industrial activity. No decrease in general industrial activity can be observed.

nor is there any definitely in prospect, except such as would naturally occur between now and the end of the year from purely seasonal influences. It may be, however, that some observers in the past few months have been over-rating the industrial activity then in progress. There has been a tenseness that should be ascribed not to the amount of work being done being extra large, but to its being difficult to do work on account of strikes and the indisposition of some workmen to work efficiently.

Small Curtailment.—Steel ingot production has now gotten back approximately to the rate of last June, the high rate of the year, and is probably slightly above that rate, which was 36,600,000 gross tons of ingots a year. The American Iron and Steel Institute reports the September production of ingots by the 30 companies that make monthly returns at 2,373,779 tons. From this it can be computed, after allowing for the producers not reporting, that the average rate of production during September by the whole industry was about 33,000,000 tons a year, against an average rate during August of 30,000,000 tons. During August production was decreasing sharply, until a rate of 25,000,000 tons or less was reached at the end of the month, while during September production was correspondingly increasing, and thus going much above the 33,000,000 ton average at the close.

If the June rate of production, the highest rate for more than a year and a half, had continued during July, August and September, the production of ingots in the three months would have been about 9,150,000 tons. The actual production was about 8,250,000 tons, showing what may for comparative purposes be called a deficit of 900,000 tons. This is about seven days of production at the present rate, certainly not enough to make much trouble, or enough to justify consumers stocking up very largely in anticipation. A consumer ought to have a leeway of more than seven days even if no strike or railroad blockade is in prospect.

Decline in Coke.—The Connellsville coke market held up until recently at a fictitious price, due to the anxiety of furnaces to get supplies, encouraged by the high prices being quoted on pig iron, although, as a matter of fact, there was scarcely any buying at these fancy prices. Coke ruled at $12 or higher for several weeks. Early last week it sold at $11 and by the end of the week it had sold at $10.50. There is much room still for it to decline. Coke has not infrequently sold at less than the market value of the coal involved, 1½ tons, plus cost of coking. Coal is now rather easy in the market at $3.50, while the cost of coking, with the very high wage scale now paid, is about $1.25. The formula would make a coke price of $6.50.

Pig iron prices have begun softening but no actual market has been developed, as consumers require a decline of several dollars a ton and have not even begun to nibble as yet. Basic iron can be bought at $30, valley. At one time it was claimed to be worth $34, though the highest sale to a consumer seems to have been at $32.50, and that was only one case. Foundry iron can be had at $32.50, while it is claimed a few stray carloads sold some time ago at $36, marking the very outside of the market.

All told, several merchant furnaces have gotten into blast, the two latest, just about in now, being Cherry Valley and McKeefrey, both at Leetonia, O. Besides the merchant furnaces, the Cambria Steel Company has been offering all grades for several weeks, and at least one other steel interest is now offering basic iron. Since consumers bought very little iron while the merchant furnaces were down, they can hardly be expected to buy much now, when various furnaces have resumed and are making deliveries on old orders. Competition will, therefore, bring pig iron prices down, aided soon by coke becoming available at reasonable prices.

In steel prices there is scarcely any change to be recorded, but the undertone is softer and delivery premiums are narrowing. When they have disappeared, basic prices for forward delivery are likely to begin yielding. Of late, merchant bars have been plainly at a minimum of 2.00c, but rumors are now going around of some being offered at 1.95c. Sales of sheets at above 3.60c have become small in point of tonnage.

Car shortage and embargoes have been the main support of the steel market in the past week or two. At many mills, shipments are not equal to production, while shipments are not well distributed, it being impossible to reach some customers on account of embargoes. The steel mills, however, are not accumulating anything like the volume of steel they had at the high point in 1920, when some estimates were that 3,000,000 tons of finished steel were piled at mills. Accumulations now are hardly one-tenth as much, and mills will not pile up much more, being in doubt whether buyers would want the steel, of the particular specifications involved, if shipped much later than the specified time.

The Steel Corporation's unfilled obligations increased by 741,502 tons in September, against increases of 173,944 tons in August and 602,769 tons in April, hitherto the record month this year for bookings. The large increase in September was due chiefly to the 100,000 ton Sinclair pipe line order and the large volume of rail business done, in anticipation of the advance in price from $40 to $43, now effective. Some of the rail tonnage was not formally entered in September, and will influence the statement for October. Unfilled obligations at the end of September amounted to 6,691,607 tons, equal to what production would be in seven months at a 70 per cent. operating rate, although of course the obligations are not uniformly distributed among the different departments. The independents, on the other hand, have as a rule, very small order books. The relative condition in this respect is much the same as that which obtained at the end of 1920.

MARKET FOR TOOLS IN HONDURAS

With reference to the machinery market in British Honduras, Trade Commissioner Stevens writes:—"The total imports of this colony under this head are negligible. Power producing machinery is represented by fuel oil engines of stationary British and American types, but importers do not carry such engines in stock because of the fractional demand. There is no agricultural machinery of any importance except the most primitive types of sugar mills, with a capacity of a few barrels per day. Even the equipment of the saw-mills is limited, and the ease of replacement of spare parts from New Orleans prevents the introduction of other lines.

"Certain limited business exists in small marine engines for use on the rivers, and in this connection a certain amount of business might be done with detachable motors. Beyond this latter opening, however, there is nothing in the machinery line to be anticipated from British Honduras at present. The only machines for which business could be expected would be light scales of American type, and sewing machines. A considerable number of standard American varieties of counter scales were noted. The sewing machines in evidence were the 'Singer' and the 'New National.'

"A considerable trade is done in woodworking tools in this colony. All timber is shipped in hewn logs, so that the demand is restricted to tools of primary manufacture. The ordinary chopping axe of the type common in Canada does not appear to be as popular as some of its odder-looking relatives. The Kentucky axe is the more common specimen. Supplementary to the axe imports, there are fairly large imports of grindstones, which might be supplied from Canadian quarries. These stones are of moderate quality and are imported in sizes of 6 to 24 inches diameter. The smallest of these stones sell at 40 cents each. Complaints were heard regarding the unevenness of these American stones, but to date no competitor has appeared to replace them.

"Some business is done in hand saws, and rather more in cross-cut saws. Mahogany cutting is single-handed sawing, and Canadian offerings of cross-cuts should be this type of saw. The Disston and Atkins houses, both of which have Canadian factories, furnish nearly all the saws in use at present."

SELECTED MARKET QUOTATIONS

News From the Industrial Field

Windsor Machine and Tool Co., Windsor, Ont., contemplate the erection of a plant at St. Thomas, Ont., at a cost of $100,000.

Canadian Westinghouse Motors will be installed at the new power plant being erected at Price, Que., for the Lower St. Lawrence Power Co.

International Combustion Co., Montreal, capital $50,000, has been incorporated to manufacture and deal in stoves, furnaces, boilers, hot water heaters, radiators and sanitary apparatus.

Linde Canadian Refrigerator Co. of Montreal, has awarded the roofing contract of their new factory at Lachine, Que., to Pilon and Beauchamp of Lachine.

The Dominion Bridge Co. of Montreal, has been awarded the steel contract for the new City Hall of Montreal; the cost of the steel work will be approximately $124,500.

The Trussed Concrete Steel Co. of Montreal, have secured the contract for the reinforced steel for the $60,000 factory being constructed for W. C. McDonald of Montreal.

The Imperial Oil Co. has awarded the general contract for the erection of an oil refinery plant at Calgary to McDonald Bros. of that city; the estimated cost will be about $2,500,000.

The Trussed Concrete Steel Co., and the Canadian Bridge Co. of Walkerville, have secured the contract for steel work for the new Leggatt and Pratt factory being erected at Windsor, Ont.

The Provincial Government has recognized the possibilities of iron mining in Ontario and has appointed a committee to investigate the prospects. The Hamilton Steel Works will shortly make a test with 43,000 tons of briquetted ore obtained from the Moose Mountain Mine.

Sydney, N. S.—The Grand Trunk Railway has ordered 29,000 tons of 100-pound steel rails for delivery next Spring, according to announcement made by the British Empire Steel Co. This, it is said, will help keep the Sydney plant going, with a force of 3,000 men, all winter.

Harris Oil Corporation, Toronto, has been incorporated with two million dollars capital to acquire, develop and operate mineral, oil and gas lands. The directorate includes Lloyd Harris, and W. T. Henderson, Brantford; Noel Marshall, D. B. Hanna, and C. J. Harris, Toronto; W. H. Magill and J. A. Thomson, Hamilton.

National Steel Car Corporation, Hamilton, reports uncompleted orders amounting to three million dollars.

Minto Coal Co., Montreal, Que., capital $1,000,000, has been incorporated to develop coal mining properties in New Brunswick, and to deal in coal, coke and by-products.

Ottawa announces that the rate of exchange on freight shipments between Canada and United States, Oct. 15 to Oct. 31, will be one-eighth of one per cent. No surcharge will be collected on international freight or passenger business.

Some cases of undue delay in delivery of Canadian Machinery to subscribers have come to our attention. This paper is mailed every Wednesday afternoon. If you do not receive your copy promptly, please advise us so that we may take the matter up with the post office.

In an educational bulletin from the Algoma district, the C. P. R. mention F. E. Veaudry, Schreiber, Ont., an engineer, for meritorious service. He repaired his engine, which became defective on the road, and brought his train through to terminal.

Canadian trade for the first six months of the present fiscal year ending Sept. 30 was $37,664,156 better than for the same period last year. Exports increased by $59,556,165. The increase in September alone was over thirteen millions. Imports showed a falling off of $14,899,514.

Gladys Belle Canadian Oil and Refining Co., Lethbridge, Alta., with capital of ten millions, has been incorporated to acquire and develop petroleum properties and to refine and deal in petroleum products. Chas. Benton Coon, of Tulsa, Oklahoma, is named as an applicant for incorporation.

Holmes & Schultz Electric Co., Kitchener, are a new concern specializing in electrical maintenance, mill and factory supplies. The members of the firm are F. O. Schultz, formerly with the Westinghouse Co., and H. W. Holmes, with Canadian Hart Products and Victor Saw.

Steady progress is being made on the new sugar refinery at Petrolia, Ont., for the Peninsular Sugar Co. The Sarnia Bridge Co. has been awarded the contract for 75 tons of steel, this to be delivered within four weeks. The steel sash and steel doors will be supplied by the Trussed Concrete Steel Co., of Windsor. The Grand Trunk siding will soon be completed.

Robb Engineering Works, Amherst, N. S., report a marked improvement in business. Orders had been received from Montreal for ten boilers, some of the Victoria type for heating large buildings and other steam boilers for power purposes. Other orders were for two large engines of Robb-Armstrong type, for a power company at Fort William and also for a number of buoys from the Department of Marine and Fisheries. Prospects are bright for further business.

Belleville.—For some months past the Springer Lock Manufacturing Co. has been working to capacity in all departments as reflecting activity in building industries. During the past summer an addition to the machine shop was erected, which increases the shop floor space by about fifty per cent. During the last few weeks a number of new machine tools arrived and are being installed in the new wing. Among the larger tools is a Brown and Sharpe Universal milling machine, with vertical milling attachment, a die engraving machine, a shaper, a large punch press, a battery of three screw machines, two dozen bench vises and a miscellaneous lot of power-driven bench tools. The company has secured supplies of raw material, coal, coke, scrap and pig iron, which fact ensures uninterrupted operation throughout the present winter, as the sales department is crowding the production department. A new pattern storage vault has recently been completed, in order to store the increasing number of patterns.

Belleville.—Elliot Machinery Co., of this city, manufacturers of woodworking machinery, state that their business has been steadily improving through the present year. This is particularly true of the domestic trade. Sales in the province of Ontario have made the largest improvement, western sales being next, while only a nominal increase was noted from Quebec and the Maritime Provinces. The company has developed a nice export business and are shipping this week twelve of their Universal Wood Workers to New Zealand. This will make a total of seventy machines to New Zealand recently. Twenty-five of these machines have been shipped to Australia. A large number of machines were exported to Great Britain until recently arrangements were made to manufacture in England. Some time ago the company designed and commenced to manufacture a household clothes washer. The latest line the company has taken up is school desks of the pedestal type with the height of seat and desk adjustable.

This Machinery List will Interest You

If you are not getting the Williams' Machinery List regularly every month you may be missing more than you realize. Each issue contains many bargains in machinery, both new and old. Each machine listed is backed by the Williams' Guarantee of "after-sale" satisfaction. Get this list before you buy again.

Better send a card today.

The A. R. Williams Machinery Co., Ltd.

64 Front Street W., TORONTO

Halifax, St. John, Montreal, Winnipeg, Vancouver

Loss by fire to the extent of about $10,000 occurred last week to the planing mill of the James Gilchrist Lumber Co. of Toronto.

National Bronze Co., Limited, Montreal, capital $50,000, has been incorporated to manufacture and deal in metal and metal products.

The McKinnon Steel Co., of Sherbrooke, Que., has been awarded the steel contract for the new power house, dam, etc., under construction, for the Lower St. Lawrence Power Co., at Price, Que. The steel plate for the same projects will be supplied by the Horton Steel Co., of Montreal.

P. H. Secord and Sons of Brantford, Ont., have secured the contract for the construction of the main Arts building for the Western University at London. The estimated cost will be $450,000. The chimney for the power house will be erected by the Webber Co. of Chicago and will cost nearly $6,000.

The Foundation Co. of Montreal, has been selected as the general contractors for the construction works in connection with the work on the new pumping station and pipe line for the St. Lawrence Pulp and Paper Co. at Three Rivers, Que. The cost of the undertaking will be about $200,000.

Kingston.—The Canadian Locomotive Co., Ltd., have taken on one hundred and five men, in the last few days, for locomotive repair work. The general manager, William Casey, states that Canadian roads are inquiring about new locomotives and there is every prospect that orders will be received at an early date. Prices of locomotives will increase with the price of steel. The company quoted a Canadian road on a certain type of locomotive on August 10th last, and on October 10th the increased cost of iron and steel had added nine hundred dollars to the cost. This is not the limit as prices are going higher yet. Mr. Casey believes that next spring locomotive and car shops in Canada will be working to capacity.

Montreal.—W. W. Butler, president Canada Car and Foundry Co., expresses the belief that Sir Henry Thornton, new head of the C.N.R., will first turn his attention to the equipment needs of the system. Canadian roads, he said, had been long out of the market, and it was obvious that a great deal of business should develop in that direction. Recent inquiry by the Grand Trunk for prices on approximately 7,000 cars is considered significant and Mr. Butler anticipated that in the course of the next two or three months, equipment companies in this country will have received orders from the Canadian roads of no inconsiderable size. The Canadian Car Company is at present engaged on repair work for the Grand Trunk on 1,500 cars with more in anticipation from that source shortly. In the matter of business from the United States, Mr. Butler was rather pessimistic, stating that new building was naturally prohibited by the tariff and that even in the matter of repair work the constant changing of tariff regulations at Washington would likely make such work impossible. There does loom up for the company, however, prospects for export business, that is to various parts of the British Empire. The last export order that the company received was that from the Soviet Government last year, an order which amounted to about two million dollars.

AUSTRALIA ADDS TO REDUCED RATE LIST

Under recent by-laws issued by the Department of Trade and Customs, Australia, the following are added to the list of materials and articles which may be imported into that country at reduced rates of duty if used in the manufacture of specified goods, or for specified purposes within the Commonwealth:—

(Continued on page 46)

The Pyrometer From the Standpoint of the User

Thermocouple Principle Now Generally Employed—Electric Welded Couples Give Best Results—Instruments of Great Assistance to Furnace Operators—Protecting Tubes from Gases

By A. N. ARMITAGE

NEARLY all the articles dealing with the subject of pyrometers have been written by people who were financially interested in some particular make of instrument, and however impartial they may have tried to be, they have at least failed to mention imperfections or disadvantages to be found in the particular type of installation in which they were interested.

The thermocouple principle is now almost universally employed as a means of measuring heat in the steel industry except for very high temperatures such as the temperature of molten metal in which case, optical pyrometers are used. All the makes of pyrometers now on the market have their good points, the question is, which kind, if any, is the best for our particular purpose. It is possible that a system which would be satisfactory for use in the ceramic industry would not be of much use for the treatment of steel. The indicating and recording millivoltmeter perhaps is the simplest measuring instrument and the one which requires the least attention from the operator. We now have a single point recorder which requires almost no attention except to keep the clockwork wound up and a little cleaning and oiling when the roll of paper is renewed.

The millivoltmeter employed should be of sufficiently high resistance to take care of the resistance of the lead wire which varies with the temperature to which the lead wire is exposed and also with the length of lead wire used. If the instrument is located near the furnace and compensating lead wires are used, a low resistance instrument can be employed and will give sufficiently accurate readings, but if it is necessary or advisable, as is often the case, to locate the measuring instrument at some distance from the furnace, an instrument of much greater resistance will be necessary to read the true electromotive force of the couple.

Using Heads Repeatedly

A pyrometer system arranged so that couples can be made up at the plant probably is more economical in operation than the one in which the couples must be purchased completely assembled. The different parts, including the time of the operator taken to make up and calibrate the couples, do not cost nearly so much as new couples, and new couples must be calibrated also. The heads can be used repeatedly. Couples, can also be shortened a few inches when the ends become burned off or when the couples are found to be incorrect on checking.

We have an instrument in connection with four coal-fired pit furnaces which was made to be used with shunted couples, and as we often have to run the furnaces at very high temperatures to reach the Acm point in hyper eutec toid steels, the couples were very easily destroyed and new ones had to be bought. It was found that cromel-alumel wire had a millivolt-temperature curve that was very similar to that of the couple of the instrument in question. By carefully calibrating the cromel-alumel couple against the couple intended for the instrument, a shunt was made for the millivoltmeter so that correct temperatures were recorded and couples made up at the plant could be used.

These couples would read correctly only between the temperatures of 1,550 and 1,800 degrees Fahr.; the slight error recorded when the heat was rising and falling was not important. A double throw switch is arranged so that either one of two shunts can be used, one to be used for high temperatures and the other for the draw.

At first some trouble was had in twisting the ends of the wire being used to make up the couples, especially with the No. 8 wire. It was found, however, that by clamping the two wires about ½-inch apart in an ordinary vise with about 1½ inches to be twisted and, after first hammering the wires for the first turn of the twist then holding them with a monkey wrench, a twist could be obtained equal to that of couples received from the factory.

Electric Weld Gives Best Results

An electric weld is better than an acetylene weld for couples and we are welding our couples by using the rheostat on the optical bench. Disconnecting the wires from arc lamp, we connect two insulated wires to the rheostat, one of them to the couple and the other to a discarded piece of carbon from the arc lamp. A package of borax completes the outfit and good welds are very easily and quickly obtained.

A single point recording millivoltmeter is used in connection with six drying ovens used for drying molds, and the recorder can be transferred to any one of the six ovens through a six-point switch.

At first the firemen were not interested in the pyrometer at the drying ovens but now they swear by it and the molds are thoroughly and uniformly dried. The only occasion for complaint regarding the condition of the molds since the pyrometers were installed was, when the light in the instrument case burned out during the night and the firemen could not see to read the temperatures.

It has been found that when the different pyrometers are kept in order, the operators at the furnaces depend almost entirely on them, which is as it should be, especially on coal-fired furnaces where the physical strength of the operators is the principal requirement. The pit furnaces previously referred to are operated by a gang of huskies who refer to the temperature as so many pounds instead of degrees. They are given a schedule showing the required temperature at each hour as for example:

10:00 a. m. 1200 degrees Fahr.
11:00 a. m. 1210 degrees Fahr.

Annealing Forgings

In annealing or treating very large forgings or castings, special effort is made to have the hot junction of the couple touching the metal being treated and protected somewhat from the direct flame. For castings such as press cylinders, bare couples are used so that they can be twisted or turned in any desired direction. For instance, a bare couple about 12 feet long is placed with the hot end of the couple inside the cylinder so that temperatures on the inner wall can be obtained. The couple is then covered with wet fire clay along its length to protect it from the flame.

The temperatures at the car type furnaces are recorded on 12-point potentiometer recorders except when we have occasional demands for temperatures higher than 1,600 degrees Fahr. In a treatment where temperatures higher than 1,600 derees Fahr. are desired the recorder is run to this point, the couples are then removed from the furnace and the temperatures taken with a pyrometer ball. Our own pyrometer balls are made from wrought iron stock and are very accurate so much so that if there is occasion to doubt the accuracy of a couple during the progress of a heat, a ball is taken at this point. If a couple and the ball do not check, the offending couple is substituted for another.

The potentiometer is undoubtedly the most accurate instrument for measuring temperatures, line resistance can be neglected and closer readings usually can be made. The type of potentiometer provided with a cold junction compensator is very dependable, the only objection being the care required to keep the instruments in working order.

In making up couples of the iron-constantin type, it is desirable to use some kind of powder in the protecting tubes

INDUSTRIES REPORT GOOD LABOR DEMAND

THERE was a fairly brisk demand for farm labour in the provinces, mainly for threshing and filling silos, while a few vacancies for fruit pickers were offered at Oshawa and in the Niagara Peninsula, according to the Bulletin of the Government Employment Service for August. In addition, numbers of men were transferred to the prairie provinces to assist in the harvesting of the wheat crop. In the construction groups, the erection of homes and public buildings continued to afford employment in the building trades and at Kitchener, Peterborough, Port Arthur, and Ottawa, there was a slight shortage of experienced bricklayers, plasterers and carpenters.

Labourers for road and highway construction, and bridge and dam improvements, were in demand at various points, especially at Pembroke, Timmins, North Bay, Toronto and Cobalt.

Railway construction and extension work in the vicinity of Cochrane and Kippewa gave employment to workers from Timmins, North Bay and Cobalt, while railway maintenance gangs were required at Toronto, St. Thomas and Oshawa.

The offices reported that prospects are bright for employment in the logging group during the winter. At many offices, especially at Pembroke, North Bay, Toronto and Timmins, several large orders for road cutters and bushmen have been received and no difficulty is anticipated in securing experienced workers. At Cobalt a few vacancies for miners were easily filled.

In the manufacturing groups, many sawmill and pulp mill workers, and yard labourers, were required at Pembroke, Port Arthur and Timmins. At Oshawa, moulders, polishers, trimmers and assemblers, for the automobile industry, were in demand, while at Toronto numbers of skilled machinists, electric workers and skilled factory hands, were employed. A few workers for the canning industry were placed at Chatham, while at Toronto and Pembroke expert woollen weavers and garment workers were required.

There was a demand for sailors at Sarnia with few applicants to fill the positions. Calls for cooks, waitresses and institutional workers, were fairly numerous at Toronto, Hamilton and London, while the demand for casual workers showed little increase.

AUSTRALIA ADDS TO REDUCE RATE LIST

(Continued from page 43)

Materials and minor articles for use in the manufacture of the undermentioned goods within the Commonwealth:—(Provided security is given by the owner that such will be used for that purpose only, and that evidence of such use be given to the satisfaction of the collector within six months, or such further time as the collector may allow, after delivery by the customs)—Knife plates, ledger sections, for use in the manufacture of reaper threshers; calcium chloride, for use in manufacture of refrigerating materials and general purposes; tubes and rods, insulating, except of hard rubber, for use in manufacture of electrical apparatus and appliances; wedge wire for use in manufacture of maltsters' kiln floors; Paris white, for use in manufacture of paints, porcelain glazes and fluxes; steel tubing, locked jointed (a) round, exceeding 1 inch internal diameter, and (b) rectangular or square; for use in manufacture of bedsteads; aluminium plates and sheets, plain, satin-finished and/or polished, for use in manufacture of metalware and general purposes; zinc sheets, for use in manufacture of metalwork and for general purposes; steel wire (bright), half-round, for use in manufacture of wire shoelaces; wheel rims (plain, undrilled and unenamelled), for use in manufacture of motor cycle side cars.

Machines, machine tools and appliances:—But not the motive power, engine combination, or power connections, if any, when not integral parts of the exempt machines. Accumulators (storage) having plates 14 3-8 inches by 13¾ inches, for use in production and distribution of electricity from brown coal. Balling machine, semi-automatic, for balling cotton, silk, linen, wool, etc., of any shape, and with or without wood or paper centres. Crushing machine for treating of prickly pear. Dies wire drawing. Glue distributing machine and glue boiling apparatus connected therewith, for the manufacture of pianos. Shaping machines, metal working, over 24-inch stroke. Testing machine, for testing strength of paper. Cherry pitting machines. Bin-aural instrument, for detection and location of sound.

Tools of trade for artisans and mechanics and tools in general use:—When not wholly made of wood, and not being machines:—Manure drags and hooks (similar to hop and potato hooks).

The above specified minor articles, machine tools and parts, and tools of trade, are now admitted (for the purposes specified) free of duty if from the United Kingdom and at the rate of 10 per cent. ad valorem if from any other country.

PYROMETER FROM THE STANDPOINT OF THE USER

(Continued from page 44)

to exclude gases as the couples last much longer when the powder is used. We use dry fireclay and the only trouble experienced was in getting the powder into the pipes. The couple heads of this particular type were evidently designed with the idea of keeping everything out of the pipes but we finally decided to make up some tubes with the hot end threaded instead of plugged. The thermocouple was first inserted by standing the pipe upside down, pouring in the powder and closing the end of the pipe with a pipe-cap.

GENERAL ELECTRIC CO. MAY LEAVE TORONTO

CANADIAN General Electric Company may move their plants from Toronto to an outside centre, where their operations may be carried on to more economic advantage. The Toronto plants represent an investment of more than one million dollars, and in normal times they employ four thousand men. Peterborough, where the main manufacturing plants of the Company are located, is making a strong bid for the Toronto branches.

Discussing the matter with Canadian Machinery, J. J. Ashworth, general manager, Toronto, stated that when the Company first located there, they selected a site on the outskirts of the city. Due largely to expansion of the industry, that section of the city was built up, value of property increased and also assessment and taxes. Yet, the Company claims, their land is of no more value to them now than it was twenty years ago. In Peterborough, they have, at present, plenty of land available for additional plant; a new power house was recently installed for their exclusive purpose on the Otonabee River, and operations, on the whole, could be carried on much more cheaply. There is also a branch at Rockford, Que., where labor and other conditions are better.

Should the company decide to move, the Toronto property would be disposed of. As against taxes, the interest at 6 per cent. on one million dollars' investment, or $60,000, is little more than a drop in the bucket. It is this ever mounting tax bill that has practically decided the company to make a move.

There is another phase of the matter, but one which probably has little to do with the company's attitude or intentions. So far as contracts are concerned, they practically owe Toronto nothing. It is stated that they have received no consideration, whatever, from the city in this particular. Regardless of the problems attending their operation here, the city has bought wherever it could secure equipment at slightly lower prices. On the other hand, there is said to be no evidence that other cities adopt this course. It seems to be considered good policy, all things being about equal, to patronize, first, local concerns who have their investment in city property and contribute to the upkeep of city homes.

While the company has made no definite decision, the next move would seem to be the city's business.

If the outer corner of the drill wears it shows that the speed is too high and therefore it should be reduced. This is especially emphasized when drilling cast iron. Drilling cast iron can be done at a little faster speed than for steel but the corners must be watched.

PORT HOPE ONTARIO

Heavy Duty Grinding With

NORTON GRINDING WHEELS

It Makes No Difference:

CASTINGS may be large or small. They may be malleable iron — annealed or unannealed. They may be grey iron. They may be steel — carbon steel, manganese steel or any alloy steel.
MACHINES may be swing frame, pedestal or flexible shaft.
SURPLUS MATERIAL may consist of sharp fins, and long gates, or only rough scale to be "Cleaned off."

For UNIFORMITY, SPEED and ECONOMY, Norton Crystolon or Norton Alundum grinding wheels will meet all the conditions.

The abrasive, grain and grade will depend on the size of casting, its composition, style of machine used, and speed of wheel.

Make your own test of the wheel we recommend.

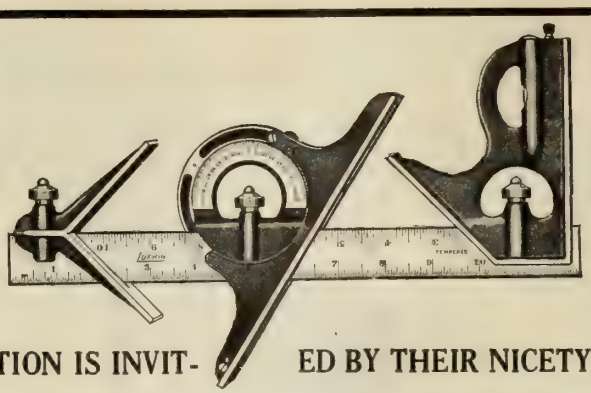
LUFKIN

COMBINATION SQUARES



LUFKIN

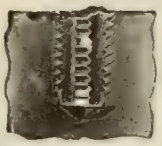
BEVEL PROTRACTORS COMBINATION SETS

YOUR CLOSE INSPECTION IS INVITED BY THEIR NICETY OF DESIGN AND FINISH

You will then see, among other improved features, center head with both legs exactly same length and ends formed, insuring accuracy on any circumference, large or small. Double protractor readily convertible into single protractor, serving perfectly for every sort of work.

THE LUFKIN RULE CO. OF CANADA. LTD. WINDSOR ONT.

Buried in the Work and Broke!



Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

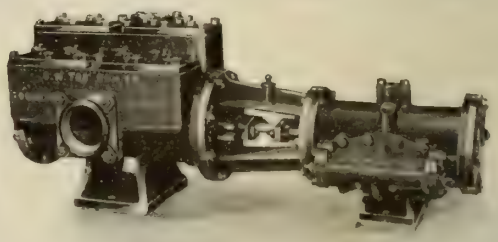
Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

The Walton Co.
Hartford, Conn.



The only Self Draining Steam Pump Made in Canada

Minimize Pump Troubles!

YOU don't have to put up with troublesome and costly pumps—pumps that leak and are in constant need of adjustment.
Your solution is in the Hepburn Patent Vacuum Pump. It requires very little attention; there are no tappets or levers to give trouble; the valves are very accessible and the long strokes assure a decided steam economy.

Write us for a complete list of features as well as particulars of Hepburn Engines, Compressors, Cranes and other Machine Shop Equipment. Information will be freely given.

Buying made easy

By grouping together these manufacturers of Special Machinery, Gears, Gauges, Dies, etc., we are making buying easy for you. Here you have a directory of the firms who can fill your requirements on any of these lines. When you are in need of any of the above, consult the firms listed here

CANADIAN MACHINERY

Buyers' Directory

143 University Ave. - - Toronto

$5 May Save You $500 or $5,000!

You work hard for the dollars you save. Properly invested they can be made to work hard for you. But they must be properly invested.

If you feel the need of a guide to show you how to invest your money to bring you the biggest return consistent with safety; to show you how to avoid the pitfalls of investment; you need THE FINANCIAL POST.

It will give you a personalized investment service. Its articles every week will tell you what you want to know about investing. Its discussion of current business and national problems will give you a new angle on economic and political questions. You will have too all the privileges of the Investors Inquiries Department. You may ask as many questions as you like about your own investment and financial problems—the standing of your broker, and the analysis of particular securities, insurance problems, etc. This service is free to all readers.

Stop losing money on bad investments. Invest $5 now where it may save you $500 or $5,000. Pin a $5 bill to this ad. (or your letterhead), write your name and address and we will send you THE POST for one year (52 issues).

THE FINANCIAL POST 143 University Ave. Toronto

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

TRADE PMS MARK
THE "RED RIBBON" BELT
TORONTO, CANADA

Low Ultimate Cost

With Great Strength, Pliability, Better Adhesion to the Pulley and Remarkable Resistance to Effects of Heat, Cold and Moisture

These considerations all present themselves as reasons for the adoption of "P M S", the "Red Ribbon" Belt, in your plant.

Wherever you find a combination of hard work, difficult drives and the necessity for fighting the bad effects of heat, cold or moisture, there you have a situation that calls for

"P M S"

If there is such a situation in your plant, if you have tried ordinary belting without obtaining satisfactory results, we would like to talk with you.

Your problem, put directly up to our belting engineers, will receive immediate attention. Write us, now—to-day, before you forget about it.

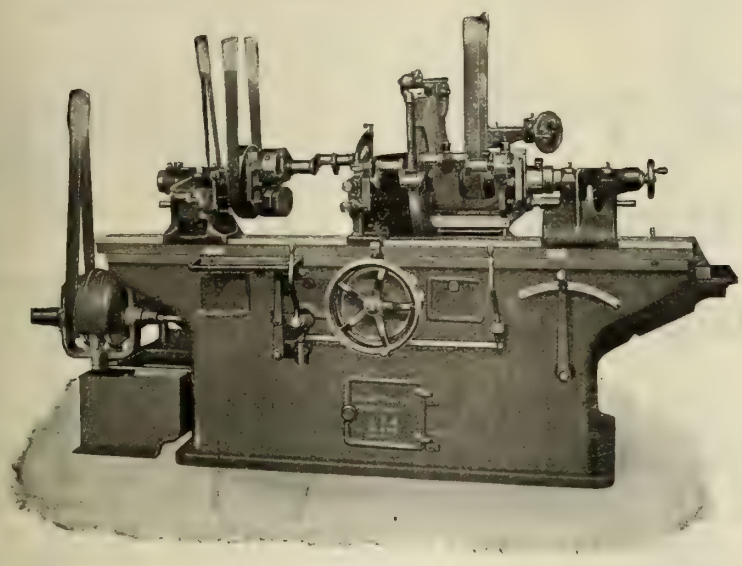
A Favorite in the Motor Repair Field



LANDIS 4-A

Special Grinding Machine

Wherever it is installed; in Garages, Service Stations, Repair Shops, etc.; this LANDIS 4-A SPECIAL is busy every minute of the day making all the repairs on every motor that comes into the shop. Its range makes it a prime favorite.

It is specially adapted for re-grinding crankshafts, pistons, piston pins, piston rings, valves, valve stems, push rods, transmission gears and piston valves. Internal jobs can also be ground by holding work in chuck or faceplate.

"Interesting Facts on Re-grinding" is free on request--write for it.

LANDIS TOOL CO., Waynesboro, Pa.

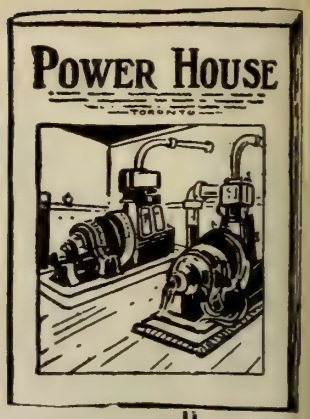
Raymond Springs

Stay On The Job

Designed by engineers who have specialized in Spring requirements, and manufactured under conditions that permit unique facilities in heat treatment, testing, etc.; it is but natural that RAYMOND SPRINGS should have earned a reputation for accuracy, efficiency and durability—that they should be known as the springs that "Stay on the Job."

You are free to consult us—our facilities and experience are at your disposal.

Raymond Mfg. Co., Ltd.
Corry, Pa., U.S.A.



DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

Save Money and Machinery by Correct Storage

Save labor, be sure of clean oil, eliminate fire hazards—and buy less oil—by using Bowser Piston-Type Measuring Pump for handling oils.

Accurate measurement saves oil; Bowsers are accurate. Oil-tight construction eliminates losses—Bowsers are oil-tight. Spillage means waste—Bowsers prevent spillage. And such a battery of oil tanks as is shown saves hand labor—cuts down operating costs and overhead.

Full details, as to exactly how much money you can save per year, and how soon the Bowser equipment will pay for itself, will be supplied by our engineering division. Ask for illustrated Folder C-13, and state your problem briefly.

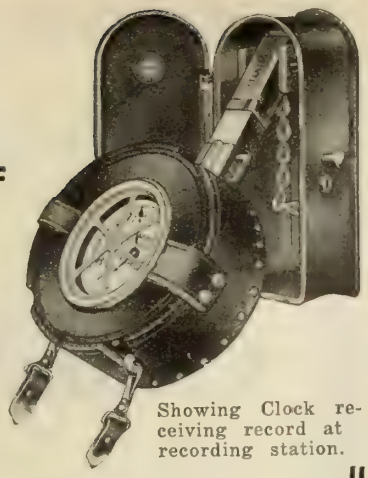
PORT HOPE ONTARIO

Watch Your Watchman!



Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful. There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.
Send for Catalogue C.M.

Why Don't You Write?

HARDLY a week passes that Canadian Machinery does not receive copies of this paper returned by the postal authorities because of the change in firm names or the address of some whose names are on the mailing list. Sometimes complaints reach us of the non-delivery of mail matter. It is not till the receipt of such complaints or the return of the paper, as the case may be, that we obtain any knowledge of the changes or removals of persons or firms. The adoption of the co-operative spirit on your part by notifying changes would make things a good deal more pleasant for both parties. The MacLean Publishing Co. want their mailing list to be in such shape that they will be able to render the perfect service to their subscribers. There is a lot of valuable trade matter mailed by this company and if you don't receive it—well, the fault is entirely yours.

ARMSTRONG DOUBLE JAW
Improved Chain Pipe Wrench

The Armstrong was specially designed to eliminate some of the weak points which extensive use and exhaustive tests have developed in the ordinary Chain Pipe Wrenches, especially the tendency of the jaws to work loose on the bar with resultant "spreading" of the rear end of the jaw and "wedged" or "jammed" chain.

Greatly increased bearing of jaw sockets upon the bar, combined with two hardened alloy steel bolts, holds the jaws of the Armstrong solidly in place even under the most severe use.

MANUFACTURING NEWS

VOL. XXVIII, No. 17 OCTOBER 26, 1922

Continuous Operations on Sensitive Drill Press

Difficulty Experienced With Hand Operated Machines—Automatic Control of Spindle Movement—Special Indexing Fixture for Small Work—Intermittent Relief When Drilling Deep Holes

APPLICATION of the automatic principle to sensitive drilling dates back only a comparatively short time, as the difficulties to surmount in this direction are invariably greater than in other branches of shop practice. Considerable success, however, has been achieved by the Kingsbury Manufacturing Co. of Keene, N. H., who have been working along these lines for many years.

The high speed sensitive hand drilling machine is one of the recent developments in production tools, yet it is necessary for the work to be performed by a highly skilled operator, as great judgment is required in maintaining the right pressure on the drill to minimize breakage. In the automatic machine the spindle pressure is controlled as readily as under the hand of a skilled operator. When the spindle is released the drill is automatically brought to the work at as rapid a rate as the drill will stand without injury; as soon as the drill strikes the work the feed through the metal is governed by the weight pressure, hardness of work, and cutting capacity of the drill. When the drill breaks through the work it is held back from a too rapid feed, which has the same effect on the drill as the hand operator letting up on the pressure. The drill is then raised rapidly and retained at the top of its stroke until released by the operator.

Special Drill Fixture

Fig. 1 illustrates the automatic sensitive drilling machine operating on small parts held in a special fixture mounted on the two tables of the machine. The table is indexed automatically after the drill has been raised from the work. Each of the two spindles operates independently and the feeding of the drill is accomplished by a weight located on the lever at the top of the machine; this weight is adjustable and exerts a constant pressure from the moment that the drill engages the work until it has completed its operations. The spindle is carried down to bring the drill to the work, and returned after the drilling of the hole, by means of a combination of levers and a friction-driver crank disc, which operates as follows: when a piece has been placed under either of the spindles, the operator pushes the rod below the table, which results in throwing the latch F out of engagement with the end of the arm that is connected to the weight lever by means of a connecting rod. The action of the weight pressing downward causes the friction-driver crank disc to come in contact with the driving member.

Near the middle of the vertical shaft which carries the driving pulley at its upper end, is a worm that meshes with a worm wheel carried at the center of the shaft on which the two grooved friction driving members are mounted. When the crank disc at each side of the machine is carried down into engagement with the driving member, the disc is rotated through the frictional action of the grooved contact surfaces of these two members.

Where articles are to be manufactured in large quantities the method of handling during machine operations is of vital importance. Automatic equipment assures continuous machining and the possibility of error, due to the human factor, is reduced to a minimum. By conserving the energy of the workmen by mechanical appliances the output is correspondingly increased.

Operation of Machine

With the two-spindle machine shown, the method of procedure is to load the jig under one spindle and start the operation by pushing in the starting rod, and then to do the same with the other. By operating the spindle alternately, non-productive time is reduced to a minimum, thus effecting a substantial improvement in the rate of production.

When the point of the drill comes into contact with the work, the resistance offered to its penetration is sufficient to lift the friction disc out of engagement but still keeping it in light contact with the driving member, thus engaging the friction drive and placing dependence on the action of gravity to feed the drill through the metal. When the drilling operation has been completed and there is no longer any resistance to the advance of the drill, the weight once more establishes tight contact between the crank disc and driving member, and through the link mechanism provides for rapidly lowering and then raising the spindle to the starting point. When the spindle has been raised to the top of its stroke the latch F snaps in under the end of the bell-crank arm, thus stopping the operation until the starting rod is once more pushed in.

Efficiency Device

In setting up the machine for the performance of a specified drilling operation, the automatic efficiency device is set to provide for stopping the machine if the use of a dull or improperly ground drill is causing the drilling time to extend over more than the proper predetermined period.

The arrangement of the device is shown in Fig. 2. Secured to stud L on which link F is pivoted, there is a ratchet wheel M which is engaged by two pawls. One of these is actuated by an eccentric connected to the feed control shaft, while the other is a retaining pawl that holds the ratchet wheel in position against the tension of a spring, as it is turned by the first pawl. If the drilling operation is completed within the specified length of time, the returning of the drill to its starting position causes a lever to lift both of the pawls out of engagement with ratchet M, so that the spring may return this ratchet to the starting position, which is determined by means of an adjustable graduated disk N carried on stud L between the ratchet wheel and the frame of the machine. As the ratchet snaps back to its starting position, a pin on the side of the ratchet comes into contact with a pin on the side of disk N which arrests the backward movement of the ratchet.

Should it happen that the drill has be-

come dull, thus preventing it from accomplishing the drilling operation within a specified time limit, forward rotation of the ratchet M is continued. A pin on the opposite side of this ratchet comes into contact with a corresponding pin carried by lever O and swings this lever over into such a position that a lug on this lever is ready to engage the end G of bellcrank lever I and, although allowing the completion of the present cycle, prevents further operation of the machine and notifies the operator that satisfactory working conditions are not being secured. Lever F carries a spring plunger P that runs over a pin mounted on the hub of lever O, to provide for holding this lever in either of its two positions. In order to restart the machine, the operator has to pull up on handle O, thus causing plunger P to first move inward and then latch the lever in the operating position. With an arrangement of this kind, it will appear that a constant safeguard is placed upon the efficiency of the operation.

The capacity of this drill depends on the nature of the work. It is rated to take drills from 3/16 in. down to 1/16 in., but larger and smaller drills have been economically used. The tool may be adapted to almost any class of work but it is especially serviceable on castings, forgings and other metals which vary in hardness. The machine has operated at the rate of from 1,000 to 3,000 holes per hour, varying with the character of the work.

Fig. 3 shows a diagram of the drill action. When the drill strikes the work it automatically slows to the drilling feed. After breaking through it again comes under the control of the eccentric and is held to the maximum feed. The curve is that of a special cam designed to feed the drill efficiently in the shortest period of time if a positive feed were used. It is thus indicated how the actual drilling feed takes care of itself while all the idle time is controlled by the eccentric.

In drilling deep holes it is necessary to raise the drill to relieve the chips and promote better lubrication in order to prolong the life of the drill. This is done by designing the cam with a "hump" on the downward stroke.

PRACTICE ON LOCAL QUENCHING

As Recommended by the American Gear Manufacturers' Association

Local quenching is merely the immersion of the part desired hard or toughened in the bath. The parts desired soft are allowed to cool naturally in the air, either to cold, if considerable softness is desired, or allowed to cool below the critical temperature Ar, before immersion, if only moderate softness is the objective.

Similarly, as with local carburizing, some of the clay and sodium silicate mixtures may be applied to the part desired soft. On quenching, the coating will usually stay on long enough to slow up the quenching rate of the part covered. Sheet metal strips or collars may be wired over the part desired soft. It is necessary, with these methods, that some of the water of the quench, if water is used, shall turn to steam and by so doing will prevent contact of further water.

Pinions may be hardened on rods or long bolts. The rod is held by the tongs and pinions and rod quenched together. This will usually leave the bores soft. A little clay between pinions and at ends of rod will help, if found necessary. Localized streams of the quenching fluid may be forced against the part desired especially hard, with good results.

As a warning, in all local heating, or quenching, strains caused by unequal contraction and expansion are set up in the work and cracking is liable to occur. This is more pronounced with the steels which harden directly than with the carburizing steels. The core of the latter, being a more ductile metal, can stand the sudden deformation better.

In connection with bearing metals it has been shown that while the liability to failure of the oil film can be minimized by careful design and operation it cannot be entirely eliminated. The danger is always present and a knowledge of the conditions that follow the suspension of the oil film is essential to the intelligent selection of a babbitt.

Demand for New Designs in Production Machines

Customers Beginning to Look Ahead—Labor Shortage Will Create Call for High Speed Equipment—Farsighted Builder Will Lay His Plans for Future Output—Figuring the Costs

"WHILE there still seems to be a sufficient supply of the ordinary type of machines, the demand for labor-saving and high production machines is improving. New designs are being sold with less effort than old types."

Thus does E. F. DuBrul, general manager National Machine Tool Builders' Association, Cincinnati, summarize conditions in the machine tool industry as regards equipment. He adds that demand for consumer goods is strong, that the prime commercial paper rate shows a slight turn upward, that labor shortage continues and wages are sure to go up, that shortage of effective supply of fuel will limit production in some lines, and that transportation is becoming a serious problem.

Dealing with the stronger demand for consumer goods Mr. DuBrul states:—"As usual in a depression, stocks were depleted and the merchants bought from hand to mouth; they did not anticipate their wants and now find it advisable to stock up again. The upturn in interest rate is due to borrowing to finance increased business. The increase in pig iron production, unfilled orders of the U. S. Steel Corp., postal receipts, freight car loadings, bank clearings, and railroad earnings, all show the upward trend.

"It now becomes a question for each machine tool builder to forecast when he is going to feel his demand with corresponding strength. It always has been later than other industries, as we know. The scarcity of labor in general is sure to create more demand for machinery to do the work that the country and the world want done. Some of our group charts show certain types of machines to have been going out for some months past at even better than the average of the 7 years before the war. The only thing that makes this total look like dull business in those lines, is the additional capacity put on to take care of the war business.

"The forehanded machine tool builder will calculate how long his stocks will last at the present rate of demand and will lay his plans for future production. He will base his calculation of profits on future cost, particularly taking into account the prospective costs of material, labor and fuel.

* * *

"**Labor:**—We hear no more of unemployment. The building boom has absorbed all the floating supply of common labor. So many contracts have been let for building that it will not be surprising to see some people disappointed when wages were down some months ago many began making plans, and by the time the contracts were let there was still ample supply of labor and material. But so many had the same idea at the same time that there were more contracts let than could be filled within the anticipated time. Those who are most pressed by their needs are going to bid the highest for labor, and others either have to stay back and wait until those needs are filled, or else meet the wages offered.

"However, this runs up the cost of building and new contracts will not be let on the basis of the high costs, and then the building boom will flatten down. In the meantime, the labor demand in other industries is quite strong and the general supply quite scarce, so that wages are sure to go up. The man who does not take this into account for his future operations is going to find himself disappointed in his profits.

* * *

"**Material:**—We see the beginnings of another price activity in iron and steel. The coal and railway strikes cut down production. While some of the increase in unfilled orders of U. S. steel is due to inability to ship, a lot more of it is due to increase of orders arising from business activity. The strikes caused a scarcity of iron and steel in the spot market and naturally prices have reacted upwards.

"Some men figure the material in their product at the cost of purchase, instead of figuring it at market price and taking the difference between cost and market into a 'Loss or gain on Purchases' account. Suppose they have been fortunate enough and forehanded enough to purchase a supply of material at a low price when there is no demand for their product from their own customers. Suppose the market has changed and costs have advanced perhaps 30 per cent. If they then base their prices with a certain profit added to this low cost, they merely transfer to the purchaser a profit that they made as speculators or forecasters of the material market, and may not get a profit as manufacturers or converters of that material.

"The only way to figure costs of manufacturing is to take the material into cost at the market price, and not to take it in at cost unless the two happen to coincide.

* * *

"**Fuel:**—With fuel reserves all depleted, there is a natural pressure to get coal. The railroads are not yet able to handle it as fast as the miners can produce it. Even coal actually loaded is not an effective supply of coal. It has to get to the furnace first, and transportation trouble makes scarcity at the point of consumption. Industries that have no reserves are very fearful of shutdowns, such as happened in the iron and steel industry. Coal is worth more money when men haven't any reserves than it is when they have reserves and can afford to wait. It isn't going to do any good to talk about coal profiteers or coal "bootleggers." Men pay the price that coal is worth to them.

"Attempts at government price fixing are not mere harmless diversions for political effect—they are harmful diversions. They lead people to think that they can get cheap coal, and then when coal is higher due to natural causes, the disillusioned buyer gets angry at somebody.

"If all artificial restraint were removed from the coal market, the price would be quite high for a while, and the most pressing needs would be supplied at that high price. High prices would bring into production a lot of coal mines that do not produce except at a high price. When their production comes on the market and restores the balance between supply and demand, the price comes down. Buyers will not buy and store coal in summer when they can get it cheaply, so they must expect to pay high prices right along until they have learned their lesson.

"The fuel situation is going to restrict coal production some more. The wages of miners are so high that a lot of men are leaving other industries to work around mines, preferring long periods of idleness as long as they can get wages high enough to keep them during the idle time.

* * *

"**Transportation:**—The predicted car shortage is upon us, and will get stronger for some time to come. The railroads have not enough locomotives to haul traffic in proportion to the needs of the country. The shopmen's strike diminished the effectiveness of the short supply of locomotives. Besides that, there is a shortage of freight cars needed for full movement. On top of all that the crop is large and relative demand for cars has increased. If to this accumulation should be added a bad winter we are going to find the transportation factor to be a serious handicap to business.

"The forehanded man is going to be getting in his materials, as there will be a strong demand from people who have not anticipated their wants. Those

Modern Foundry Well Equipped With Air Tools

Molder of To-day Relieved of Much of the Drudgery of Past Practice—Application of Pneumatic Equipment Largely Responsible—Saving Effected in Many Ways

By F. H. BELL

PRESENT day foundry practice reflects the progress that has been made in many lines of mechanical equipment for increasing production on a more economical basis. First place, in this connection, must obviously be conceded to the universal application of pneumatic appliances that have been developed to relieve the foundryman of much of the drudgery associated with molding of a generation ago. Many varied applications of compressed air are now found in the foundry, and to the adoption of this labor saving power medium can be traced the improvement in many other branches of industry that are dependent on the "sand man" for their source of supply. Not only has it resulted in greater output at less cost but it is more or less responsible for the marked improvement in every grade of casting produced.

To enumerate all the different uses to which air has been applied in the foundry is beyond the scope of this article, but it is sufficient to mention a few applications that have proved beyond doubt their worth in making the modern foundry an efficient integral part of the metal industry.

The original air machine for supplying the blast for melting the metal was undoubtedly the bellows. This device while not in general use for this purpose now, is still one of the most useful of the molders' tools. It is, however, doomed to at least partial extinction in the near future, owing to the recent development of the air-gun.

It is only within the last few years that air ramming of molds became general. The old method of hand ramming was tedious and costly and sapped the energy from the workers. To-day the portable air-operated devices for this purpose and similar operations are producing molds of higher quality and at least cost.

On tests made on this class of work it has been shown that it is possible to ram about five molds with a pneumatic rammer to one by the hand method. On a foot pound basis the ratio is approximately 40 to 1, the air rammer delivering 28,000 ft. pounds per min., while the best the hand-operated rammer can do is less than 800 ft. pounds per min.

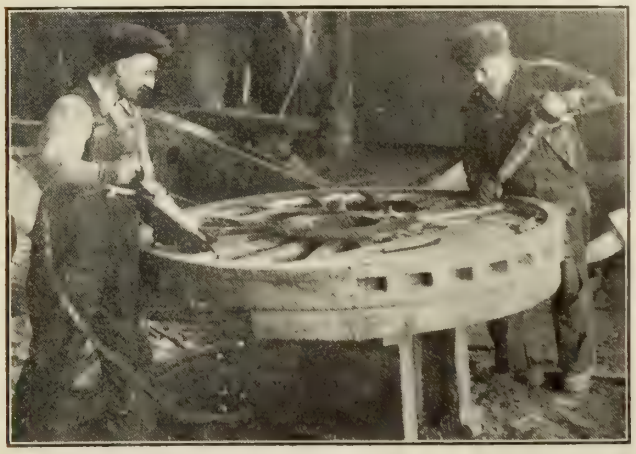
The life of an air-operated rammer depends upon the care taken of it by the user. After a rammer has been in service and it is to be laid away for a time, it is advisable to immerse in carbon oil, and when again required it should be thoroughly oiled with lubricant through the throttle handle. This practice will materially increase the normal life of the tool.

The chipping and cleaning of iron and steel castings constitute two of the most important applications of compressed air to the betterment of foundry practice. The iron castings are generally delivered to the fitting shop comparatively clean except for fins and oversizes, as the adhesion of sand and loose metal is seldom seen on iron castings, while it is nearly always present on castings made of steel. In the case of iron castings the chipping of fins is an easy process as the metal is brittle and breaks freely from the body of the piece. Steel castings, on the other hand, are tough and it is necessary to drive the cutting edge of the chisel through the metal. For these reasons it is advisable to use a harder hitting hammer on steel than on iron. The 3-in. stroke tool is best adapted for steel castings while the 2-in. works satisfactorily on cast iron. A fair example of pneumatic hammer efficiency may be gathered from the fact that a steel roll under the old hand method required several men's time for a week to clean; the same work is now performed by two men, using 3-in. stroke hammers, in about 8 hours. It is possible for an operator to guide his chisel with comparative ease and work in places that would be impossible to reach by the hand-chipping method.

Every up-to-date modern foundry is piped for compressed air the same as it is for water, and every spot where a workman is likely to be employed is provided with a tap and hose connection. When compressed air is installed the molder uses it to advantage in place of the bellows but does not obtain the highest efficiency when using the ordinary nozzle, as it is difficult if not impossible to regulate the flow and the pressure. In using the hand bellows it is comparatively easy to create high pressure in spurts by suddenly closing the bellows, an action that has become an art with many molders. This is what is required of the compressed air device.

The Air Gun

The illustration shows how this is accomplished. The little coil spring keeps the valve in place when not in use, but the real force which closes the valve and keeps it closed is the pressure of the air in the hose. The full force of the air is held back by this valve, and the operator simply presses his thumb upon the cap or button to open it. If he desires to deliver the extreme pressure of the air in order to dislodge some obstacle he opens the valve completely, allowing the air to come out in a spurt at full force and at greater velocity than is possible with the hand bellows. If a light blast is all that is required, the flow of air can be regulated accordingly. The air gun is now an indispensable tool in the foundry as it can be used for removing the debris when chip-



Removing fins from locomotive drive wheel, centre.

The air gun.

Fettling work on a large steel casting.

ping and cleaning castings, for blowing the dust and dirt from between pasted-up cores, and for innumerable other purposes.

Cleaning Large Castings

The two illustrations here shown will give the reader an idea of the class of castings which are being turned out of Canadian foundries at the present time. These castings are made of steel and it is obvious they are large ones. Every foundryman who has ever worked on steel knows that the high temperature at which it has to be poured makes it impossible of any foundry, however carefully managed and operated, to produce castings that are more than ordinarily smooth, so it will be readily seen what a proposition it would be to chip these castings by hand, as it must be remembered that steel does not yield to the chisel as readily as cast iron. Had this been an iron casting it would have worked easier but would have been a big job at that.

The larger of the two castings shown is a plunger cone for a Larner-Johnston hydraulic valve the largest ever constructed. It was cast by the Canadian Steel Foundries and delivered to the Dominion Engineering Co., the builders of the valve. The piece is 13 feet 11 inches in diameter and 7 feet 2 inches deep, and weighs about 25,000 lb. It was a perfect casting but required the services of the pneumatic chippers to make it really presentable for machining.

The other view is that of a locomotive driving wheel centre. Before the piece can be machined it is necessary to remove all fins and remains of risers from the main portion.

The adaptability of air to foundry service is almost unlimited. There is the oil-air torch for starting fires and pre-heating ladles; the air riddle; air-operated tampers; molding machines; sand-blasting and many other uses.

Hobbing Gears of Condensite Celoron

By M. E. Dalton, General Manager, Dalton & Blach

SUCCESSFUL hobbing of silent timing gears of condensite celoron material, while a very simple operation when thoroughly understood, is dependent on several factors, the most important of which is accuracy. As spiral or helical gears are used to give a continuous engagement between gears it is essential that the angle cut is right. This is obtained by a very simple formula. Next to be considered is tooth-shape. This is taken care of by the hob manufacturer. Tooth to tooth spacing is also very important, but this gives no trouble as long as one is not too economical in installing his equipment and gets a good hobber. The usual care should, of course, be exercised in maintaining exact face parallels, eliminating eccentricity of gears with relation to axis thereof and perfectly rounded and true peripheries maintained, as is our practice, by using indicator test lathes when turning up the blanks before cutting the teeth. The arbors on which blanks are set up for tooth cutting must, of course, be perfectly true and rigid always.

Greater latitude as to back lash is permissible by comparison with metal gears, and it is generally found that a back lash tolerance of from three to [illegible] thousandths secures the best results when cutting condensite celoron.

We find that the Lees-Bradner gear hobber with fast head is very well adapted for cutting timing gears of this material. The use of this equipment allows the gear man to run the hob at a very fast speed (about 260 r.p.m.). This is a very important fact, as this material machines better at a fast speed and the cost of cutting is greatly reduced. To illustrate: Take a thirty-tooth Buick crank gear on a hobber; the hob revolves once for each tooth on the gear and, as there are thirty teeth, the r.p.m. divided by the number of teeth would give you the number of revolutions of the gear per minute. Each time the gear revolves it travels past the hob according to whatever feed is used. A feed of .100 in. is used and has been found very satisfactory in practice. If hob r.p.m. is 260 divided by number teeth 30 = 8 2/3 revolutions of the gear per minute. 8 2/3 x .100 feed = .866 in. feed per minute. As the gear is one inch wide it is plainly seen that your cutting time will be less than one and one-quarter minutes per gear. These hobbers also handle any angle gear readily and do not require special long arbors for steep angles. They also have fast head index for gears which have a small number of teeth in conjunction with the regular indexing device.

It is very important that the figures in hobbing these gears be carried out far enough to insure not over an error of .00004 as it is very imperative that the angle be right to assure a bearing all the way across the angular face of the tooth at the pitch line. Formulas for figuring this class of work may be obtained easily and we sometimes furnish them.

We use a larger diameter hob than recommended for the fast head on Lees-Bradner machines, usually 2¾ in. dia. This should be recessed to clear the collet on the fast head and also to clear the nut which holds the hob on. The hob should also be tapered off on the end which strikes the gear first. Left hand hob should be tapered off on the bottom and a right hand hob at the top. While a left hand gear can be cut with a right hand hob and vice versa, still, best results are obtained by using hob of same hand as gear.

Hobs should be kept sharp, as a dull hob will produce a ragged or rough-looking gear. A sharp hob cuts more accurately as the material is resilient and will push away from a dull cutting tool. These are good reasons for high cutter speeds and fast feeds. When producing gears of one inch face thickness, our gears are ordinarily cut five at a time, which makes necessary only one backing disc of fibre to assure a clean finishing cut on the last gear of the set up as the hob comes through.

The use of a little oil on the hob serves to keep the fine dust from floating all over the place, and gives a better appearance to the machined surface.

Generating Steam by High Voltage Current

Several Large Installations Operating Successfully—High Thermal Efficiency—No Chemicals Required—Interior of Boiler Easily Inspected—No Scaling or Erosion of Tubes or Shell

THE "Electro" steam generator described below is the result of several years' tests and experiments by F. T. Kaelin, chief engineer of the Shawinigan Water and Power. Company, Canada, and has been developed in the United States by the Electric Furnace Construction Company, Philadelphia. It is an apparatus for generating steam in any required quantity at any specified pressure by means of alternating current which is led directly into the water to be evaporated. A number of large installations are in successful operation, including one of 20,000 kilowatts capable of raising 60,000 pounds of steam per hour at 130 pounds pressure.

The "Electro" generates steam by the passage of high voltage alternating current between specially designed electrodes immersed in water. The resistance of the water to the passage of this current converts it with almost unbelievable rapidity into steam, so that saturated steam at any pressure can be delivered from a generator occupying only a fraction of the space required by a fuel burning boiler of the same steam-producing capacity. The amount of steam generated, the pressure, and the amount of electric power used are governed by the height of water in the tank or the depth of immersion of the electrode in the water. The flow of water and consequently, all the required conditions for operation are controlled by standard valves.

Efficiency of Generator

The "Electro" operates at an average thermal efficiency of 98 per cent. to 99 per cent. On one installation tested in service, the efficiency of generator, steam connections and about 100 feet of the steam line was over 98 per cent. This was measured on kilowatts used and steam passing through Bailey meter. Power can be used for this generator from any alternating current, although the actual voltage determines to a large degree the individual design of each generator.

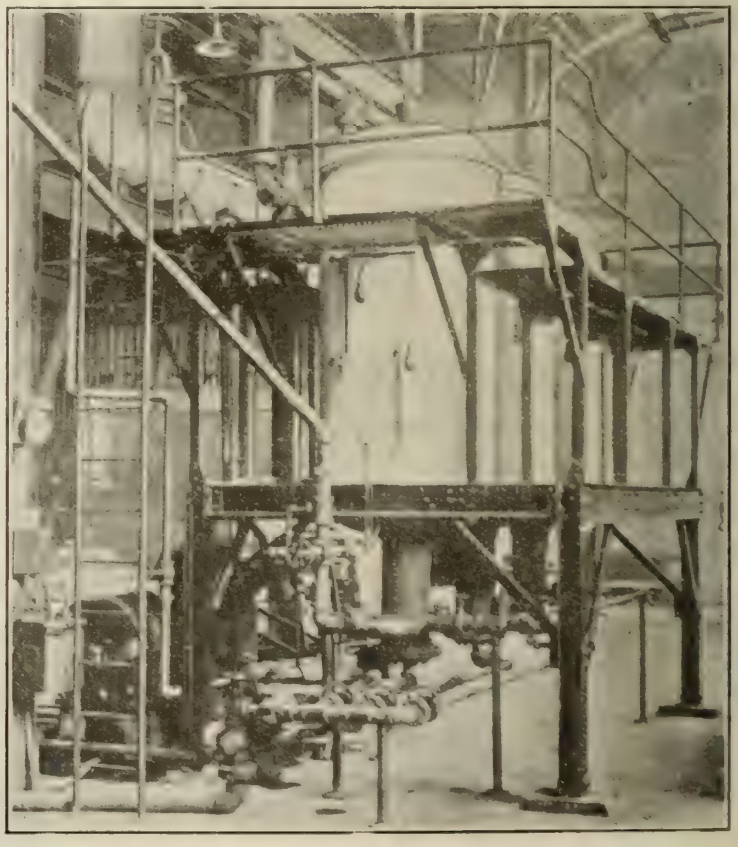
Any water that is suitable for the ordinary boiler is satisfactory for the "Electro." No chemicals are necessary for doctoring the feed water; in fact they are detrimental to its operation. Where condensate is used, a negligible fraction of the supplied water is constantly bled from the generator to prevent accumulation of sludge and foreign matter. A slightly larger amount is bled if raw water is used, but since this waste is only a few degrees above the temperature of the feed, the heat loss is negligible. Valves of special design are used to automatically bleed the necessary amount. Using ordinary water, the average time required to raise full head of steam starting cold is approximately 30 minutes.

The generator is designed, constructed and inspected with the best steam engineering practice and in accordance with the A. S. M. E. code.

No part of the "Electro" is exposed to a higher temperature than that of the steam. Inspection of the interior may be made readily by removing the bolted-on head. The only part of the boiler subject to wear is the electrode, which may be replaced annually at a nominal cost. There is no scaling or erosion of tubes or shell due to high temperatures.

The most important application of the "Electro" steam generator will be found in industries located within the range of hydro-electric power plants where use can be made of surplus energy or water running to waste. A large majority of firms contracting with power companies for blocks of electric power at a fixed rate per horsepower year have a portion of this energy, which is paid for, idle a part of every day; under present conditions a large percentage of this power made available to them, may be idle 24 hours per day. Either condition represents an ideal application for the generator. The generator may be connected up to present steam mains so as to take over the steam load from one or more coal-fired boilers, depending on the amount of electric energy available, or it may be arranged to operate independently in isolated places or where sufficient electric energy is available to shut down all the coal-fired boilers.

In some cases the hydro-electric power companies are taking advantage of surplus power and installing these generators in central locations and distributing steam to a number of nearby industries, selling the steam at a fixed rate per 1,000 lbs. In other cases, where an individual customer is a large user of steam, the power company has installed the generator in customer's plant. A number of Canadian firms have installed these steam generators, so as to make use of their surplus power. This surplus may be available for short periods only, but due to the flexibility of the "Electro" unit nearly 100 per cent use may be made of it.



"Electro" Steam Generator

Inadequate Rail Service Retards Production Growth

Great Volume of Freight Offered, and Long Decline in Expansion Two Causes of Present Problem—Too Much Government Regulation—Locomotive Power and Car Capacity Less

AN INDIRECT explanation of the activity in railway buying that has been taking place in the United States, and a definite opinion as to the handicap placed upon business by inadequate transportation facilities, is offered by Samuel O. Dunn, editor of Railway Age. Discussing these problems at a symposium held by business paper editors, he said:—

"At a time when most people are rejoicing because general business activity is reviving, it is not pleasant to be obliged to express the opinion which, however, I do express, that, because of lack of transportation, there will not be, and cannot be, any such increase of production over commerce in this country in the months and years immediately ahead of us as there have been during corresponding periods of business revival in the past.

"There is no better measure of the increase which has occurred in any period in the volume of production and commerce than the increase in the volume of freight shipped in that period. In the ten years ending with 1907, the increase in railway freight business in this country averaged 14 billion tons carried one mile annually. In the next ten year period, that ending in 1917, the increase in freight business averaged almost 16 billion tons carried one mile annually. The average increase per year in the twenty years from 1897 to 1917 was almost exactly 15 billion tons carried one mile.

"In the latter part of that twenty years the railways had greater and greater difficulties in handling the normal increase in their business. Congestions and so-called shortages of cars ceased to be merely occasional and sporadic, and became chronic.

"In order to increase the business handled, the government assumed operation of the railways at the beginning of 1918. In spite of all the efforts made under government operation, it was found impossible to increase the freight moved in 1918 more than two-thirds as much as what had previously been a normal increase. In 1920, with the railways again under private operation, the managements exhausted their utmost resources in efforts to handle all the business offered. They again increased the freight moved, but they failed by a substantial margin to move all that was offered. The average increase in the amount of freight moved annually, in the three years ending with 1920, was only five billion tons carried one mile, or only one-third of what had been the normal annual increase during the preceding twenty years.

"Now we have a large freight business offered again. What is happening? The railways are putting forth the utmost efforts to move it, and they are not yet quite equalling the record made in 1920. In due time, if the conditions remain reasonably favorable, they will equal and surpass that record. But consider what these facts mean. Never prior to 1917 did the railways, when business was large, fail to move an amount of freight which substantially exceeded all previous records. Now, they are finding it extremely difficult to equal the record of 1920, although in the three years ending with that year they increased the traffic handled only one-third as much per year as they had previously increased it for twenty years.

"Although the coal strike and the shop employees' strike have aggravated the present transportation situation," said Mr. Dunn, "they have not created it. It is mainly due to two series of developments. The first of these is the very large increase, within recent months, in industrial and commercial activity and, in consequence, in the freight offered to the railways for movement. The second is the long decline which has occurred in the expansion of the railroads. If all the locomotives and cars now owned by the railroads were in normal conditions, they could not handle anywhere near all the freight that is being offered to them, and which, in the months ahead, will be offered."

"To what is this situation due? Statistics are always tiresome and often confusing, but I must give you some to show what has happened. Probably you have seen statistics showing that year by year for the last twenty years the number of new locomotives and cars put into service has rapidly declined. It has sometimes been answered that the new locomotives and cars have been more powerful and larger than the old ones, and that therefore this decline in the number of new ones acquired does not show a corresponding decline in the expansion of the capacity of the railways. Let us then use statistics regarding the increase in the total tractive power of locomotives and the total capacity of cars. In the five years ending with 1907 the average annual increase in tractive power of all the locomotives in service was 128 million pounds. In the seven years ending with 1914 the average annual increase was less than 75 million pounds. In the seven years ending with 1921 it was only 63 million pounds. In the year 1921 it was less than 39 million pounds.

"Now, take the capacity of freight cars. The average annual increase in the total capacity of all the freight cars in the country in the five years ending with 1907 was five million tons. In the seven years ending with 1914 it was less than 3½ million tons. In the seven years ending with 1921 it was only one million tons. In 1921 it was only 500,000 tons.

Capacity Has Declined

"These figures indicate clearly how increases in the power of locomotives and capacity of cars have declined until they have almost ceased. The development of the other facilities of the railways has declined in equal proportion. The increase in the total tractive power of locomotives was less than one-half as great in the seven years ending with 1921 as in the seven years ending with 1907. The increase in the total capacity of freight cars was only one-fifth as great in the seven years ending with 1921 as in the seven years ending with 1907. No man in his senses can expect the railways, in view of these facts, to deal successfully with anywhere near as large an increase in freight as they easily dealt with when business revived after the panics of 1893 and 1907, and after the depression of 1914 and 1915.

"It was long predicted by those who opposed the policy of restrictive railway regulation that in time it would result in making railroad transportation the limiting factor in production and commerce in this country. That prediction, unfortunately for everybody, has now been completely fulfilled. Almost every other condition is favorable to an increase of production and a revival of prosperity such as we had after the panic of 1893, after the panic of 1907 and after the depression of 1914 and 1915. The railroad situation makes impossible for the present any such increases of production and commerce as occurred then.

Government Regulation to Blame

"This limitation upon the country's prosperity and development must be removed. How can this be done? The answer is simple and obvious. The influences which have reduced and almost stopped the expansion of the railroads must be removed. Much the greater part, or all of this reduction of the expansion of the railroads has been

(Continued on page 23)

Selection of Babbitt and Maintenance of Bearings

Rebabbitting of Worn Bearings—Method of Aligning Shaft—Babbitt Formula for Electric Motors—Selecting Grade for Special Purpose—Unequal Pressure on Main Shaft Hangers

By W. S. STANDIFORD

THERE are many repair jobs on small machines which, on account of wear on their bearings, require to be "done over again at intervals;" the rebabbitting of boxes on small engines, nail machinery, etc., being among them. After having had a number of rebabbitting of crankshaft shells that were lined up in the usual slow manner, the writer devised a simple and rapid method of leveling shafts, it having been used on numerous occasions with good results as regards the working of the finished machine. Drill two holes opposite each other in both boxes to fit small brass machine screws, place the shaft into position using a level to get it straight, turning the screws in or out until it is level. The usual methods adopted by workmen to prevent molten metal from running out the bearing ends should then be taken. Turning the screws as needed enables very quick work to be done. The shaft may be then removed for warming and put back into place on top of the screws with an absolute certainty of its being level. These brass screws ought to be left in altogether after pouring of the hot metal, as they prevent the threads in the cast-iron retaining shells from getting filled up with babbitt, thus making rapid work possible in replacing new bearings when the old ones are worn. The screws are easily removed when the bearings are worn, as new ones will have to be inserted into the threads for each rebabbitting job when it is necessary.

Motor Bearing Formula

An extra fine electric motor lead base bearing metal babbitt which will run well in an atmosphere of from 90 to 100 deg. Fahr., and give the least amount of trouble in operation is appended. This metal is made out of a mixture of lead and antimony combined with a small amount of tin. Lead and antimony are metals that have a chemical affinity for each other, which property causes them to combine in all proportions without any impairment of the anti-frictional qualities of either. The antimony also confers hardness to the lead, thus enabling it to stand a high rate of speed in a factory without abrasion and heating of linings taking place provided that care be taken by workmen in pouring the hot metal, etc, and dirt is kept out of all all bearings during operation of the machine.

Babbitt bearing formula for electric motor operation in a 100 deg. Fahr. atmosphere:

450 lbs. lead.
155 lbs. antimony.
6 lbs. tin.

It must not be inferred from the foregoing that the above babbitt is only suitable as a bearing lining for machines working in a warm atmosphere, as a matter of fact, it will be found to be of great service for motors and dynamos running in ordinary locations. Should any additional toughness be desired, the tin can be replaced by an equal amount of copper, although it will be found that this metal is tough enough to give good results without any copper.

Judging the Quality

In judging the quality of any babbitt whether it is bought ready made or manufactured on the premises, a good shop way of sizing up its excellence or otherwise, as the case may be, is to examine a bar's fracture when broken. First-class metal should show a fibrous fracture [illegible] white oxide patches. If any bar's fracture contains such patches it denotes that it has been poorly made and is worthless in regard to giving good service in bearings. As a general rule a babbitt with a large tin content will show a lighter surface when broken, as contrasted with a lead base one. All babbitts will also "streak [illegible] more or less, if they are pressed hard enough upon it. However, those that contain the most lead will make the blackest mark. This is a rough shop test for lead contents.

Selecting the Grade

As a guide in selecting a grade of babbitt for any type of machine regardless of whether their parts operate with a jerky motion or otherwise, it is best to get a very tough metal, one having a tin base proves excellent. A mixture composed of 85 per cent. tin, 6 per cent antimony and 4 per cent. of copper will give good service in places where a constant shock is imparted to the bearings. To find out if any babbitt metal is tough or hard, whether it is made upon the premises or purchased ready made hammer a cold bar back on itself until it assumes a U shaped form. A tough metal will show no cracks under this treatment. It ought not to dent easily and will ring when struck against a piece of other metal.

Class of Service

Another point that many factory managers overlook when buying a ready-made metal is that they fail to state to a manufacturer the purpose for which it is intended, and when they find it to be unsuitable they put the blame upon its quality as being N. G., when, as a matter of fact, it is really their own fault as they should have stated what it was to be used for. The writer ran across a case like the above a number of years ago when the bearings of an engine were babbitted with a ready-made article which proved not adapted for the purpose and ran badly, causing considerable trouble. The engine was rebabbitted with another brand and gave no further trouble. The remaining bars from the first lot were laid aside and later on used by the millwrights on another machine, the condemned metal giving good satisfaction in regard to wear. Unless any executive is thoroughly familiar with the varieties of babbitt marketed, and their adaptability for different classes of machinery, it is better policy on their part to state to a manufacturer what class of machinery it is to be used for, giving him details as to speed, etc.

Placing Responsibility

This procedure puts the matter of responsibility upon the maker as to the wearing qualities and gives him a chance "to make good" his advertising assertions, such a course being "fair and square" to all parties, as it avoids injustice to a manufacturer's product, which may be a high-grade article but performs badly on machinery to which it isn't suited. It sometimes occurs during the making of babbitt that small particles of copper and antimony amalgamate into hard pieces; these are generally no larger than a pin head in size, they possessing the property of a fairly hard steel. Sometimes they are located upon a bearing's surface, at others are a short distance under it. As the babbitt wears away these particles are sure to score the shaft. Long continued heating and stirring at a proper temperature will cause them to mix with the other ingredients and do away with this annoyance.

Main Shaft Bearings

There is one class of bearings in factories which are subjected to the roughest kind of usage, and that is line shafting with its rows of pulleys belted to a number of machines. As it is an impossibility to keep all of the belts at the same driving tension it naturally follows that some hanger bearings will have a greater pressure exerted upon them than the others, with excessive wear taking place on their bearings. Besides this disadvantage, these bearings always collect dust to a more or less extent, which stops oilholes in fast and loose pulleys and makes hot bearings. In order to reduce such trouble to the lowest possible extent, experience indi-

Tension and Working Strains of Belt Fasteners

Value as a Transmitting Medium—Only Fraction of Actual Strength of Belt Needed for Delivering Power—Various Grades of Belts Considered—Maximum Load on Fastener

By ERNEST D. WILSON, B.Sc., Ph.D.

THE VALUE of belting for transmission work is determined by its gravity and its horse power transmitting qualities rather than by its tensile strength. If this were not so, it would be comparatively simple for a belting manufacturer to combine certain materials and produce a belt with a tensile strength far beyond any at the present time on the market, but such a belt might have little or no value as a power transmitting medium. It is very interesting to note that in no case, in a very large series of tests conducted by the Mellon Institute and at Cornell University on power factors with the power transmission of belts, has a tension of over 1,000 pounds per square inch been obtained, even under loads several hundred per cent. larger than the rated capacity of the belts. Since the tensile strength of most belting materials is almost invariably more than 3,000 pounds per square inch, it is evident that only a fraction of the actual strength of the belt is needed for transmitting power.

The same thing applies to belt lacing. If strength alone were desired, a fastener could easily be designed which would never let go, but it would have little or no value as a practical belt lacing. Belt lacing should be sufficiently strong to carry maximum loads with a reasonable amount of safety. It should be durable, flexible, smooth on both sides, and should not injure or weaken the ends of the belting. Even though the use of belts to transmit power is very common, few people have a clear conception of just how and why they do transmit power. In studying the strength required of belt fasteners, it is necessary to clearly understand the mechanism and the stresses involved.

Author is consulting engineer of Clipper Belt Lacer Co., formerly of the Mellon Institute, and Chief Engineer Graton and Knight Mfg. Co.

Effective Tension

Consider a belt placed over a pulley and drawn tightly against the pulley surface. If one strand of the belt is pulled harder than the other, either the pulley turns or the belt slips over the pulley surface. The sum of the tensions on both strands of the belt measures the force with which the belt is held against the pulley face and also the friction load on the bearing. The difference in the tensions of the two strands measures the turning force applied to the pulley, and is often called the "effective tension."

As the belt is turning and transmitting power it is easy to see that the highest tension in the belt is the tension of the tight strand and any fastener must be capable of withstanding this tension, with a fair margin of safety to spare. The question then becomes, "What tensions may we expect in a belt carrying its normal load?"

Ratio of Tension Between T. & L. Strands	Effective Tension or Pulling Strain	Tension in Tight Strand	Tension in Loose Strand	Total Tension causing Bearing Friction
6 to 1	60	72	12	84
5 to 1	60	75	15	90
4 to 1	60	80	20	100
3 to 1	60	90	30	120
2 to 1	60	120	60	180

Surface of Belt

The poorer the surface of the belt, the lower is its power-transmitting capacity, and the higher the tension must be to transmit a given amount of power. Belts with good surfaces run constantly with the slack strand actually sagging and show a tension of from ten to twenty times as high in the tight strand as in the loose, whereas when a belt will only allow two times the tension in the tight side as in the loose (which unfortunately is sometimes the case) it is a very poor belt indeed, and has an extremely poor surface.

In the following table the tensions developed with belts of various grades are considered. In each case the belts were run under an effective tension of 60 pounds per inch of width, which is about the maximum recommended by the manufacturers for single leather or four-ply canvas or rubber belt.

In the table given each line shows the tensions which would exist in belts of varying quality as to surface, all 1 inch wide traveling at the same speed, and transmitting the same amount of power. In the second case shown where the tension in the tight strand is 75 pounds, the slack strand carries 15 pounds, and the belt forces the shaft against its bearing with a force of 90 pounds. Contrast this with the extreme case of ratio of two to one. The tight side of the belt must withstand 120 pounds pull and the

Form of Gear Blank Affects Efficiency of Drive

Shafts Should be Rigid and in Proper Alignment—Stiffening for Shock and Vibration—Shape and Number of Spokes—Convenience in Casting Gears—Cooling of the Metal

By CHESTER B. HAMILTON, Jr., B.A.Sc., M.E.

THE FORM of the gear blank chosen by the designer of the mechanism has a great influence on the ultimate success of the drive. Another important item which, however, does not lie within the field of the present discussion, is the rigidity and alignment of shafts and bearings which carry the gears. Springy shafts, badly over-hung mountings or bearings in bad order will greatly reduce the effectiveness of any gear drive.

Small Pinions

(a) If a pinion must, on account of the ratio, be very small in comparison to the size of its shaft, it may frequently with advantage be cut solid on the shaft. The thickness of metal over the key way, measuring to the bottom of the nearest tooth space, is usually the deciding factor. The stock from which the combined shaft and pinion are turned would practically always in such a case be a steel forging. It is preferable that the root diameter of the pinion be not smaller than the shaft in order that the cutter may pass through and clear the shaft. The minimum limit is when the outside diameter of the pinion equals the diameter of the shaft. This construction, of course, weakens the shaft seriously. The limiting condition for no weakening of the shaft is with the pitch diameter of the pinion not smaller than the diameter of the shaft. In any case, where the root diameter is less than the shaft diameter, the cutter must be sunk into the work to the proper depth before feeding it along the tooth. This applies in all cases, no matter which process is used in forming the tooth, and the machine designer must provide space between bearings for this additional cut-into portion of the shaft, the length of which varies with the process of cutting used. If the space between bearings is great and the pinion considerably larger than the bearing diameter, it is advisable to make the shafts conical, tapering from just below the root of the teeth down to the bearing diameter.

Annular Groove on Face

(b) The great majority of pinions are in the form of plain cylinders with a bored or broached hole. A better form for all but the smallest is with annular groove on each end face, occupying the space between what would be the outside diameter of the hub and the inside diameter of the rim on a gear. This makes an appreciable difference in lathe time, especially on quantity work where two tools can be working at once.

Webbed or Disc Form

(c) This form of construction carried further in gears of larger relative diameter becomes the webbed or disc form of gear blank. For heavy work subject to great shocks and vibration and not too large diameters this is a very economical type. If the face is wide or the hub long, it may be stiffened by a number of triangular gussets or braces arranged at intervals. The fillet between the web and the rim, and particularly at the hub, should be very much larger than usual if full advantage is to be taken of the strength of this type of gear. The inner surface of the rim should be as nearly cylindrical as possible, with minimum draft, or the lathe department will have trouble chucking such a casting. On medium or heavy work, four or six holes in the web, two or three inches in diameter or more according to size of gear, do not weaken it and are a great help in handling and bolting to face plate. In large work the holes would, of course, be large enough to pass a sling chain.

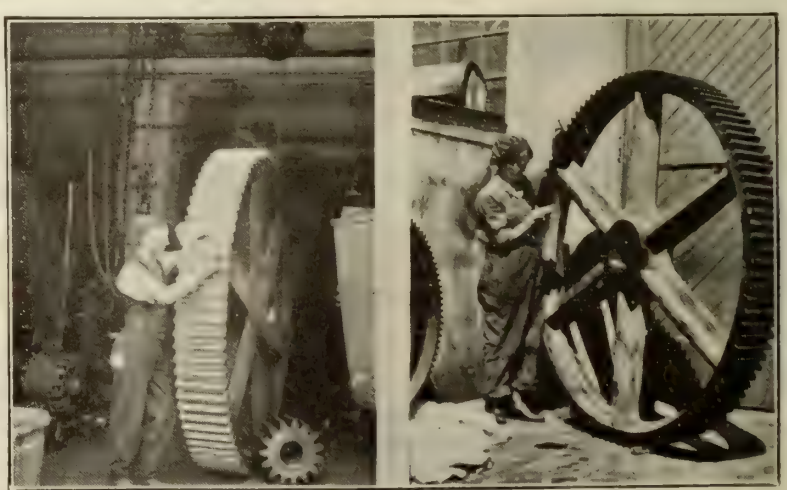
Spoke Size and Shape

(d) Most gear blanks are spoked. The spokes may be of many forms and numbers according to purpose and size. The number of spokes is usually six for small and medium gear and eight for large. The number of spokes is somewhat related to the number of teeth, for if the pitch is less the thickness of the rim will be less, and a thin rim, relatively to the diameter, calls for more points of support. British draftsmen very frequently use five arms, but the logic of this choice is difficult to see, for the number of jaws in chucks and the number of slots in boring mill tables is always a multiple of two or three and never of five, so the odd number of arms is liable to make trouble in chucking, especially when wide arms and large fillets are used.

Factors of Strength

Curved arms, intended to spring to take up shrinkage strains, were formerly much in vogue but are seldom seen now. One reason is that modern machinery averages much heavier in cross sections, relatively to diameters, than formerly, and the modern designer depends on correct proportions to prevent undue cooling strains in the foundry. In the form of transverse section of the arms the draftsman has a range of choice. Most arms are of elliptical section with the long axis in the plane of rotation. While it may be argued that this is not the most economical distribution of the metal for strength, the reason for its adoption is that a more economical form would distribute the metal in thinner section and it would cool too rapidly and pull away from the rim. This refers to the average gear. The "H" and "I" sections are commonly found in large heavy-duty gears, but it is to be noted in these cases that the economic section was not attained by spreading out the metal there would be in an oval into thinner sections, or not much so, but mostly by adding more metal to carry the greater load or shock, and adding it in the most advantageous position.

An arm in the form of a cross is us-



Left: large gear with H-shaped spoke. Right: Large gear with spokes of cross section.

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Member of Canadian Engineering Standards Association.

ually a confession of a desire for a cheap pattern, though not always. The "H" arm has the disadvantage that it will not draw out of the sand. Otherwise, it is the best for wide face gears, applying the force to the rim at two points instead of one and working in well with the provision of two circular ribs around the inside of the rim which is an advantage. This class of wheel is usually cast with six or eight segmental cores between the arms. The "I" section arm is suitable only for narrow-face gears, as it is weak laterally unless the two parallel portions are made quite wide. This works in only with a single rib inside the rim, which, again, is suitable only with a thick rim, stiff in itself, and a coarse pitch. This, then, is the field of the "I" arm. A condition under which a modified cross form would be suitable arises when the "H" would be too expensive to mould, the "I" stronger than necessary if made heavy and thick enough to avoid cooling strains, and the oval section not strong enough. Then a cross with extremely heavy fillets making it resemble an ellipse with re-entrant quarter curves, would be good practice.

Ring Gear

(e) The ring gear is simply the rim of a gear, integral with which are lugs or flanges, extending inward or outward, by which it is attached to the other portion of the mechanism which carries it. For a wide-faced gear there may be two flanges, and it may be mounted on a pair of spiders, or one spider, or on a drum, or against the side of another wheel. It is essential in the production of ring gears that the faces of the flange which are to act as locating faces, are known, and the teeth made accurately to these faces without regard to any others. Ring gears should be mounted with fitted bolts, in holes reamed after assembly, except small ones, which may be riveted. The bolts should be drilled and provided with split pins or wired in pairs.

Internal Gear

(f) Each kind of gear so far considered in this section has successively less metal within the circle of the teeth. Carrying this idea a step farther, the next class is the internal gear, which has all the rim metal outside the teeth.

In the preceding five sections only differences of form of body have been considered, but with the internal gear the form of gear and the tooth action are so inter-related that it is difficult to consider one without the other. The internal has a number of advantages over the external. First, on account of its form: the pinion being inside the gear it is located at only a fraction of the centre distance from the gear axis that would be needed for the external arrangement. The gear forms its own guard for the protection of the teeth, and can be shrouded to completely cover both ends of the teeth, leaving only a hole on the pinion drive side of diameter equal to twice the centre distance plus the pinion shaft diameter, plus clearance.

As the internal gear curves toward the pinion teeth and the external curves away, it is obvious that the arc of contact is greater with the internal. This gives greater strength, particularly with small pinions. There is also less shock and noise as the teeth enter engagement, and less friction and wear while in mesh, but these and some other advantages are due to the peculiar tooth action, and need not be elaborated in this section.

DEMAND FOR NEW DESIGNS

(Continued from page 15)

who need goods badly are now paying premiums to get them.

"All these things make it desirable not to book too far ahead at fixed prices. Cost conditions on the one hand, and demand conditions on the other will have quite an influence on future prices.

* * *

"**Equipment**:—The amount of movement in machine tool orders indicates that customers are beginning to look ahead. Demand is not yet so strong, however, as to show any great shortage in equipment generally. There is probably enough equipment of the ordinary type as a hang-over from the last boom. But labor shortage will create a demand for more productive equipment, as we have pointed out right along. New designs of high production machines are now getting most of the limited business that is coming out, and the chances are good for them to continue to do so. The old designs will not sell as well as they have heretofore, and those who have newer designs and put a stiff push behind their selling are now getting a good increase in business."

INADEQUATE RAIL SERVICE

(Continued from page 19)

due to the policy of the government regulation which has greatly reduced and narrowly restricted the net return earned by them. This reduction and restriction of their net return has driven new capital from them. Unable to raise new capital in relatively as large amounts as in former years they have been unable to develop and increase the capacity of their properties as formerly. Under the Transportation Act they were assured in 1921 a net return of six per cent. Business fell off, expenses were high, and they earned and received only 3.3 per cent. Under a ruling of the Interstate Commerce Commission it is now held that they are entitled to earn 5¾ per cent. Thus far in 1922 they have earned 4 1/3 per cent. They never can raise enough new capital adequately to develop their facilities until they earn a much larger net return. With the large increase in business that is now occurring and the shop employees' strike behind them, they probably can soon begin to earn the 5¾ per cent. to which the Commission says they are entitled But how long will it be after they begin to earn it until there will be another wide-spread demand for general reduction of freight rates?

Not Question of Rates

"The public long has been told that the railroad problem of this country was ceasing to be one of rates, and was becoming one of lack of transportation. The public, however, has insisted in regarding the problem as chiefly one of rates and in consequence cannot now get, and for a long time will be unable to get, anywhere near enough transportation. It will lose many times more in a short period by this lack of transportation than it has gained in the last ten years by keeping rates on a basis which has almost stopped railroad development.

"Do not in this crisis denounce the managements of the railroads. The farmers and business men and the regulating authorities who have done what the farmers and business men have demanded are the people who are responsible. There is no immediate remedy for the present transportation situation. It must be borne as best it can. It can be remedied in time by the adoption of a wiser and fairer policy which will let the railways earn the net returns they require in order to furnish adequate service. There is no other remedy under private ownership, and very few men wish to take a chance with government ownership."

SELECTION OF BABBITT

(Continued from page 20)

cates that a specially compounded shaft metal is better for all-around use on shaft hangers than some of the formulas given for other types of machinery. Appended is a formula of a good-wearing babbitt for this purpose.

Babbitt formula for lines of shafting:

15 parts antimony.
90 parts lead.

Some mechanics add phosphorus to the babbitt with the idea that it will cause this metal to adhere better to iron shells. Phosphorus has the above effect, but it also has the drawback of making it flow very sluggish when pouring and makes the casting full of blowholes. On this account phosphorus should not under any circumstances be added to babbitt as it is a detriment instead of a benefit. When the simple rules for doing babbitting, as given in this article, are followed, neat and clean castings will be the result regardless of the grade of metal used.

BOOKLET

The Backbone of Automobile Service is the title of a small booklet recently distributed to the trade by the Jacobs Mfg. Co., of Hartford, Conn. It has been prepared with the assistance of many prominent machine tool builders, and it is intended to promote a more general appreciation of the importance of adequate shop equipment in the service station.

Business Papers Have Inspiring Field for Service

Their Duty to Preach Gospel of Progress Through Common Effort and Thought—Bring Business Man Into Touch With National Problems—Supply Him With Facts for Sound Conclusions

THAT they have a great and inspiring opportunity for service; that they are in a position to influence business thought and to direct it into proper channels; that they can bring home to industries their dependence upon each other, and their interest in the progress of the country as a whole—these were the duties and responsibilities which Lewis E. Pierson, chairman of the Board, Irving National Bank, declared business papers must recognize in any united effort looking to better business. It was, in fact, on this question of unity that he addressed editors of American and Canadian business papers recently at their annual convention in New York.

"Over a period of seven years," Mr. Pierson said, "business operated under conditions which were unhealthy because they were temporary and abnormal. The long period of expansion established false standards for labor and capital alike, and the abrupt transition to the depression of 1921 bred discontent and dissatisfaction among labor, and induced caution approaching timidity among industrial and financial leaders.

Encouraging Reaction

"Perhaps never in our history was the change from prosperity so sudden or severe.

"Examination of the facts and figures now available for the present year shows an encouraging reaction. Turn to the reports of industrial earnings, to the volume of business done, to bank loans, to investment buying, to stock prices, in short turn to whatever index of events you please and you will find that the present year has shown a distinct and encouraging improvement over the corresponding period of 1921.

"Then compare the results for 1922 with the results for the pre-war year of 1913 and the conviction is borne home that this country, after the vicissitudes of the war, is establishing herself on a new normal level of prosperity which in many respects is above the pre-war level. It is true that in some instances profits are still lacking, but wherever the question of expense and overhead has been intelligently handled, our industries are either showing profitable operation, on a basis equal to our above the pre-war standards, or indicate that they are rapidly working into a position where profits will come shortly.

"Do not misunderstand these indications or these results as the precursors of a sudden revival of boom times. Do not imagine because we have successfully weathered one storm that the need for caution and patience has passed."

The speaker maintained that, in spite of the fact that the air was full of panaceas which proposed to solve existing problems and bring the world to a plane of greater prosperity, the man or nation that relied for a cure-all on anything but work, patience and still more work, was headed for disappointment.

"To make that work more effective should be the common aim. We cannot legislate our business into a state of blissful prosperity, but we can, and should endeavor to improve, wherever possible, the machinery of business. In that endeavor the first object should be to stabilize our business processes.

"The nearer we can come to a situation where our industries will proceed on a settled, and established level, and where the inter-relation of the various factors of our national business will be thoroughly fixed and universally understood, the better we shall be equipped to meet and deal with whatever new situations may arise.

"Sudden bursts of good times followed by abrupt periods of depression are not calculated to increase the real prosperity of a nation. They indicate that there is something wrong with the processes of national business and argue a weakness in the nation's economic structure which should be corrected.

Business on More Even Lines

"If we can arrange our affairs that the chart of national business will show a more even line, if we can fill in the hollows, and make the peaks less abrupt, it will be possible to plan our progress more intelligently and execute our program more surely.

"The business man has come to realize that the more evenly business is conducted, the better it is for everyone. And the obstacles to that orderly progress spring from a common source. Cast back over the causes of depression, over-production, strikes, ill-advised legislation, reckless competition, and you will be led to the conclusion that most of our difficulties proceed from the failure of the country as a whole to secure a thorough understanding of our national problems or from the inability or unwillingness of various sections and classes of the body politic to work together for the common good.

"The farmer, for instance, in seeking legislation which will give him higher prices for his wheat, is too apt to forget that this immediate advantage may react upon him in the higher prices which the industrial labor, which eats his wheat, must have for the products of the factory

"The labor which advances its rate for building construction pays higher rent for its own quarters.

"The railroad worker seeking an increase in wages, thinks only of the immediate gain, without pausing to consider that he is at the same time increasing the price of every commodity that he uses, which the railroads transport.

Better Mutual Understanding

"Our greatest need, then, is for a better knowledge, a better understanding of each other's difficulties, of the underlying economic laws which regulate all business, and a greater readiness to work for the general good as the surest means of promoting individual welfare.

"If we can reach a point where there is general agreement on our national problems, and where we can bring th full force of an intelligent public opinion to the solution of these problems, we can stabilize our national business.

"If we can secure a crystallized national thought which will not hunt for vague panaceas, for prosperity through legislation, for any of the artificial expedients which attempt to over-ride the inexorable laws of economics, but instead will seek progress through intelligent effort and moderate but steady gain we can look confidently to the future.

"In the creation of this national attitude, the business papers have a great and inspiring opportunity for service. Reaching, as they do, the industries of the country, they are in a position to influence business thought and to direct it into proper channels. They can bring home to our industries, their dependence on each other, and their interest in the progress of the country as a whole.

"Week after week, and month after month, they can preach the gospel of progress through common effort and common thought. They can bring the business man into touch with all the national problems which affect him profoundly though indirectly. They can supply him with the facts which will enable him to form correct conclusions not only on his own business but on the business of the country as a whole.

"Finally they can throw their great influence toward the achievement of industrial understanding which will do for industry what the Federal Reserve system has done for finance.

"Until the creation of the Federal Reserve System the country was torn from

(Continued on page 38)

Practical Ideas From Practical Men

CARE OF TURRET LATHE TOOLS

By Harry Moore

Turret lathe tools, for various reasons, have a much shorter life generally than tools used around an engine lathe. Take, for instance, the chucks, universal or independent. It is a much more difficult operation to remove one of these from the spindle of a turret lathe than an engine lathe, chiefly because there is never the same amount of room to work in. Thus many turret lathe chucks receive hard knocks which they are unable to stand, and their accuracy is destroyed. A simple device can be made up easily for this particular job. This consists of a short piece of round stock about 2 in. dia., through the side of which is drilled a 1-in. hole to take a bar of this size which is tightly driven therein. The short piece is gripped tightly in the chuck and the bar brought down sharply on a hard wood post resting on the floor. Another thing frequently seen on the turrets is the badly pitted condition of the tool holes, the result of numerous slips when driving in tight holders. This is bad practice indeed, no holder or tool should require driving into the turret hole; if a slight tapping with a lead hammer is not sufficient to place a holder, the shank of the holder should be inspected for burrs, lumps, etc., and the hole in the turret thoroughly cleaned.

In Fig. 1 a hollow mill holder is shown that can be used in many cases with a big reduction of the percentage of broken mills. The holder is bored deeper than usual so that only the face of the mill A protrudes, a hole B drilled in the bottom allowing the free exit of any chips that may work inside. Fig. 2 shows an ordinary taper shank tool holder furnished with two hardened pins A-A at the front. A holder so fitted is spared the knocked and bulged condition resulting from resting the front of the holder on the vice jaws, etc., when knocking out stubborn shanks, or shanks with broken tangs. Very often more tools are required on a job than the turret can accommodate, which means that two must be used in one hole, being removed when finished with. To avoid tightening up such spare holders, an eccentric groove A should be cut in the shank as shown at Fig. 3. The tightening screw B in the turret need then be only adjusted by hand, which means a considerable saving of time in placing and removing the holder. It will be seen that the shank tends to tighten itself automatically when the tool is cutting and is prevented from being pushed by, into the hole, by the same groove.

The flat cutter holder shown at Fig. 1 is fitted with an auxiliary collar, screw and locknuts. It is sometimes impossible to get this kind of tool to work right unless it is set in a certain position. This may be right side up, or upside down, or to the right or left at an angle; this peculiarity preventing the use of a flat on the shank to keep the tool from turning under the cut. For this purpose the collar A is used: It is held to the holder by screw B, and afterwards nuts E E and tightened and locked on the turret top as shown. Thus, any position the holder may be in at the time is fixed without relying on the regular screw in the turret, which, if tightened onto the bare shank of the holder with enough force to keep the latter from turning would soon roughen the surface quite sufficient to spoil it.

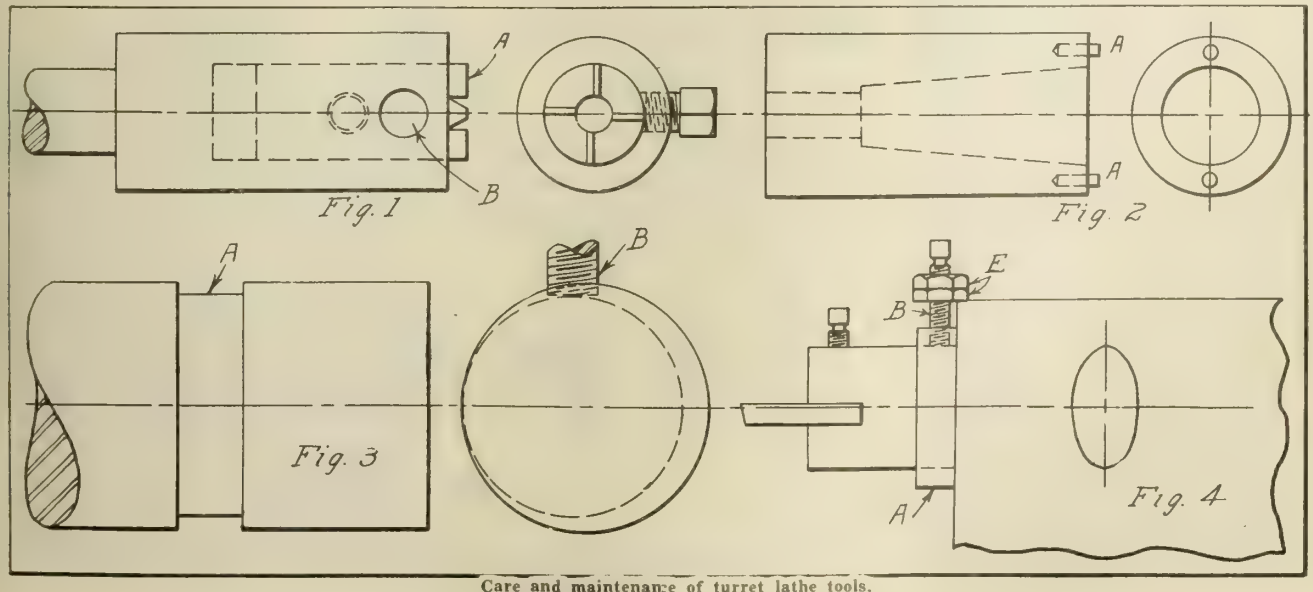
BUSHINGS FOR THE ARBOR PRESS

By D. A. H.

Most arbor presses come with a slotted plate having about four sizes of openings in it. Where arbor presses are not used for lathe work—and there are thousands of them in use on assembling or disassembling operations—the slotted plate has its disadvantages. It swings around, though this may be overcome by a pin or screw; the slots are just a little too big or too small; and the slots present only a half bearing or less to the work, so that it tips and it also results in rapid abrasion of the face. To try to press a piece in or out, have it line up square and true, and not bend anything under such conditions is almost impossible.

In our shop, we have removed this slotted swivel plate. In its place we have a casting permanently fastened. The center of this casting has a hole clear through and recessed about two-thirds of the way down from the top, leaving a shoulder from ¼ in. to ½ in. wide according to the size of the press.

If the press is used exclusively on one job, there is a steel bushing tightly pressed in that hole and left there. It offers a square working surface for the job and supports the work right up to the shaft or pin being pushed through the center. Presses on general work have sets of bushings made up for them—bushings that can be removed with the fingers and with the bore made 0.005 in. larger than a nominal size, such as 0.505 in, 0.755 in., etc. The time saved and the avoidance of spoiled work will pay for this equipment in a short while.



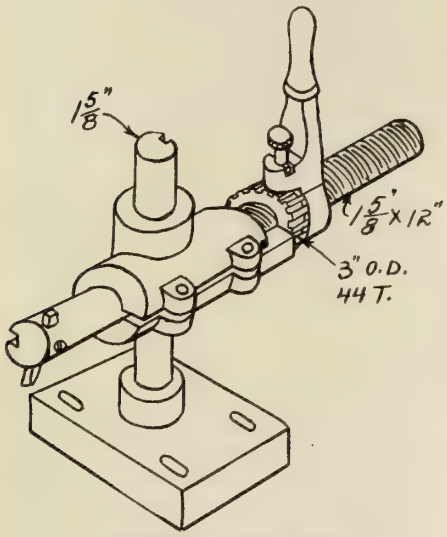
Care and maintenance of turret lathe tools.

COMMUTATOR TURNING DEVICE

By D. A. Hampson

There were quite a number of direct current dynamos and motors in our vicinity and it fell to our lot to true up the commutators when in bad shape. Besides the larger ones, there were even more of 1 h.p. to 5 h.p. size but these latter were dismounted and the armatures removed for putting in the lathe. It is of those that were more advantageously trued up right in position that we will here consider.

We had an 18-in. planer that wasn't used much and we frequently took the cross rail off, trucked it to a plant, and



Commutator turning device.

turned the commutator at night or on a Sunday, using the cross feed for turning, the vertical feed for positioning the tool, and blocking the entire rail up to bring the tool on a center line. These jobs came so numerous and the time spent changing the planer being a dead loss (for the customer) that we made up the portable device shown by the drawing.

This has a flat cast iron base which is attached to some part of the dynamo pedestal, either by tap bolts or through bolts and a clamp. Where we could not conveniently do this, we got permission to put in two or four holes to fit our slots. The upright post shown permits a wide range of adjustment in that direction for the saddle which is bored a close fit and supplied with key and set screw.

At right angles to the vertical post, is the tool shaft and bored hole to fit. For this, the casting is split and binder screws put in, making it possible to snub up as tight as the tool shaft can be fed. The far end of the shaft is cut with a 12 thread screw long enough to permit a movement of 9 inches. A steel nut is made a close running fit on this thread and has ratchet teeth cut on its periphery, to be engaged by the pawl set in the cast iron handle whose hub also rides on the threaded shaft.

An extension of the saddle casting is bored so the steel nut may be dropped in the recess and one half of it is cut away as shown. This provides the stationary member from which the feed movement is obtained. The tool shaft is splined full length. The cutting tool is held by a set screw at the near end. This device is easily portable, can be set up in less time than a machine tool slide, and its use does not tie up a machine. In the six years of its use, it has paid for itself many times over.

REPAIRING GASOLINE TANKS

By C. Howard

Should a gasoline tank, or can which has contained gasoline, need repairs for which a soldering iron is to be used, great care is necessary in charring the container of any gasoline fumes which may be in it. If extreme care is not exercised there is a possibility of an explosion occurring. Gasoline fumes being heavier than air will remain in any container for a considerably length of time even though it has an opening to the air. There are several methods of clearing away such fumes of which turning the tank with its opening to the lowest point and leaving it so for several hours is perhaps the easiest. Another way is to subject the container to indirect heat in a similar position to that stated. It is advisable however, to keep the blow-pipe as far away as possible.

TEMPERING TAPS AND REAMERS

By C. H.

A very good way to hold a tap or reamer when drawing the temper is with threaded or fluted end in a roun pair of tongs, the squared end to the flame. Draw the tool to the proper degree of heat at the point. When drawn to the proper color quench it in oil or lukewarm water, this gives the cutting end of the tool the necessary hardness to stand up under the cut and the shank the strength and toughness necessary to prevent it from breaking. For tapping or reaming cast iron draw to a light straw and for steel draw to a light brown.

REPAIRING AN OLD LATHE HEADSTOCK

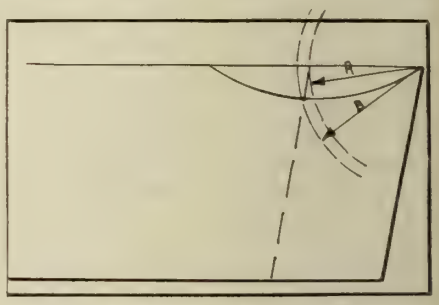
By G. Blake

The writer had to overhaul the headstock shown in the accompanying sketch and this is how it was effected: the headstock was for a 3 in. centre, hand turning lathe for wood and metal. The back stay consisted of a screw with lock nuts, and pointed at one end similar to an ordinary lathe centre and engaging in a female centre in the lathe mandrel. With constant usage the male centre began to wear away and it would frequently seize up after being adjusted to take up end play. The female centre in the lathe mandrel was trued up again and a new back centre was made, only instead of a male it was made female and a ⅜ in. dia. steel ball was inserted as shown in the sketch. The ball provided a much better thrust bearing than the male centre and the lathe spindle ran much easier and without any shake as it had less friction to overcome.

GRINDING KINK FOR THREAD CHASERS

By G. B.

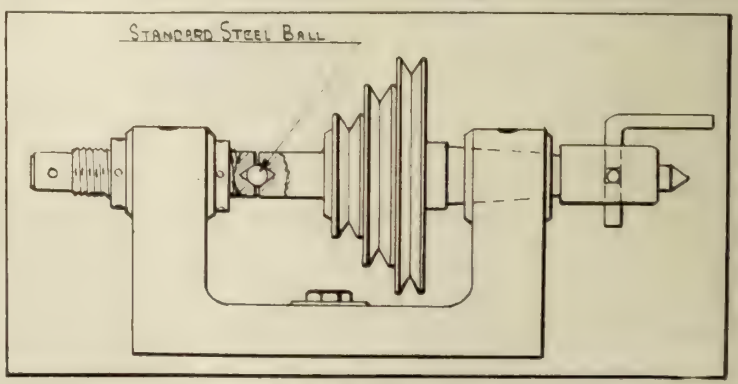
It is somtimes desirable to cut a thread slightly deeper than the standard, and it is a very easy matter to do this with a single point screwing tool, but the result will be a thin thread, diameter reduced on outside work, dia-



Kink for thread chasers.

meter increased on inside work and a poor fit on the mating part.

It is quite possible to cut a thread deeper than the standard and not affect the diameter or thickness of the thread by means of a chaser ground with a lip as shown in the sketch. The maximum or standard depth is shown at A, before the tool has been lipped. The increased depth over the maximum is shown at B. No further explanation is necessary as the sketch shows very clearly how the increased depth is obtained without sacrificing the thickness of the thread.



Repairing an old lathe headstock.

New Things in Shop Equipment

SUNDSTRAND STUB LATHE

The Sunderstrand stub lathe, though primarily designed for piston turning, may be adapted to a varied line of production. This machine, which has been placed on the market recently, is of unique design, the carriage ways being integral with the unusually heavy headstock. The bed is well ribbed and braced throughout. The spindle is of ample size and runs in phosphor bronze bearings well lubricated with wick feed from an oil reservoir. Front spindle bearing measures 6 by 4¼ by 3¼ in., rear bearing 3⅜ by 4 in. Take-up for both bearings is adjusted by means of a single nut at rear of spindle. Spindle nose is 4 in. in diameter with two threads to the inch. Spindle is driven by heavy bronze wheels and worm provided with ball bearing thrust to eliminate friction, and geared to 3 to 1 reduction. Gears furnished with lathe give spindle speeds as follows: 40-50-65-85-110-145 revolutions per minute. Provision is made for mounting an air cylinder and a quick acting draw back.

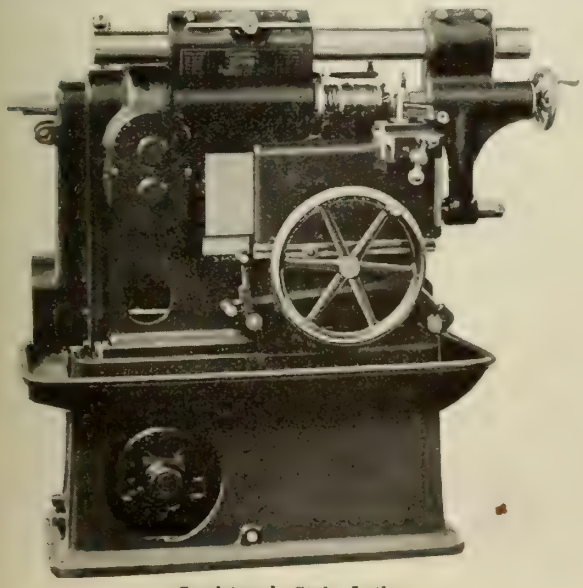
The feed is driven from the spindle by chain and pick-off gears located at headstock end of machine, and standard gears furnished with machine provide following feeds: .020, .030, .038, .050, .066, .090 inches per revolution of the spindle. Feed arrangement to carriage and rear tool is very simple, driven by worm through a large diameter worm wheel. Worm is constantly submerged in oil, and to engage the feed is lifted into worm wheel by handle conveniently located at front of machine. Worm wheel is keyed on pinion shaft that drives the carriage, no gearing required in the apron. On pinion or worm wheel shaft is a large hand wheel measuring 15½ inches in diameter.

The tripping mechanism consists of a dog on carriage which trips the feed lever and automatically disengages worm from worm wheel. This provides a reliable and accurate knockout, and a dependable one when working or facing to close diameters.

The carriage is 18 inches long with full length bearing surface on an 8 inch face at front of bed and 4 in. angular surface on top. An angular gib at bottom of carriage is provided to take up any wear, and adjustment can be made from front of machine. Front tool slide has stop screws underneath for tool adjustment, and slide is of sufficient width so that several tools can be clamped on at one setting.

The tailstock is extremely heavy and is clamped securely to the large overhanging arm and supported by means of a stud protruding from the bed. This method of supporting and locking tailstock insures rigidity and absolute elimination of vibration. A large diameter screw with a lead of 1½ inches to each revolution of the tailstock hand wheel is provided. Spindle is of sufficient diameter to withstand any tendency of spring, and has a longitudinal adjustment of 5 inches. Tailstock spindle bearing is split the full length and held in position with screws which may be adjusted to the wear of spindle. This feature does away with any chance of spindle being loose and causing chatter.

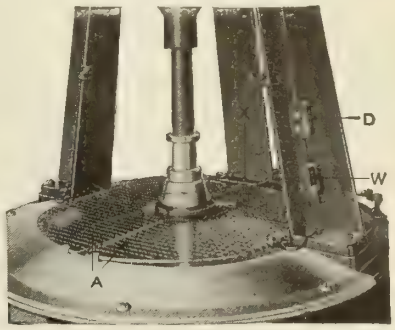
The 3½ in. dia. overhanging arm is so arranged that tools can be clamped on, as required, for performing several operations, including the facing and boring of the open end of pistons, centre drilling, etc. An adjusting rack is cut on the overhanging arm. Power is transmitted by motor direct. A 5 h.p. motor is regularly furnished, securely fastened on pivoted frame or plate inside the bed and entirely out of the way of operator. An adjustment is provided for belt tension. A friction clutch pulley is located at back of machine, mounted on roller bearings, with starting handle conveniently located for the operator when standing in position at front of machine. This machine has been developed by the Rockford Tool Co., Rockford, Ill.



Sundstrand Stub Lathe.

AUTOMATIC SAFETY GUARD

A safety device for self-balancing centrifugal extractors has recently been placed on the market. The guard consists of three essential parts. The hinged cover stands completely clear when open. The construction of the cover is such as to completely guard the basket and yet allow a clear view of the interior and permit a free passage of air to assist extraction. A loop is



Extractor Safety Guard.

connected to the belt shifter in such a way that the belt cannot be shifted by the handle and the power applied until the guard has been completely closed. A lock is placed on the spindle or shaft which automatically and positively prevents the opening of the covers until the basket has come to a complete stop. This lock makes it impossible for the operator to open the cover after shifting the belt while the machine is running or coasting. The lock is simple and so small as to offer no obstruction while loading or unloading the basket. New extractors may be ordered or guards may be applied to existing equipment. These guards are made by the Tolhurst Machine Works, Troy, N. Y.

HIGH SPEED MULTIPLE DRILL

A multiple drilling machine designed to give a centre feed over the drilling area has recently been developed and placed on the market. This particular construction provides for a true alignment of spindles and prevents the head from springing out of line from the drilling pressure. This also prevents the cramping of the head on the ways which is very important. In preventing the springing of the head, the friction between the drills and the bushings is eliminated, and thereby does away with the severe pressure, not only of the drills and connecting spindles but also with a needless strain on the feed mechanism and subsequently throughout the whole machine.

There are four optional methods of

drive:—three-speed cone pulley; three-speed change gear box, motor driven; three-speed change gear box, belt driven; direct connected variable speed motor. The main drive comes through the base of the machine, thence directly to the head gears. This avoids complication and tends to eliminate vibration. The feed is accomplished by means of a heavy ram which is directly above the center of the drilling area. The ram is moved by means of a pinion which is connected through the change feed gear box directly to the main drive of machine. The feed is driven by means of direct connected gears which operate the centre feed ram. For each change of speed, of which there are three, there are three changes of feed which vary according to different combinations from .0018 in. to .023 in. per rev. of spindle. These feeds are standard, but feeds either faster or slower will be provided to suit special requirements.

Heads of various sizes, both round and rectangular, can be furnished. These allow a liberal vertical adjustment of spindles and allow a center distance to be obtained equal to the diameter of the spindle itself. This arm is equalled by no other multiple drilling arm on the market. Universal joints are used not only on the multiple drills but are sold exclusively throughout the trade. The head is provided with an automatic safety counterweight catch which prevents it from falling in case of an accident to the cable. The capacity of the machine in cast iron is twelve 1 in. drills, or equivalent. Owing to the center feed construction, it is possible to make the distance from the center of the head of the face of the post considerably greater than as though the feed was directly from the post.

This machine can be built for tapping in addition to drilling. In the tapping model, back gears on the head for reducing the spindle speed are used. These can be engaged or disengaged while the machine is running. The operation of tapping is as follows: the operator brings the taps down into the work by means of the quick approach. Further downward movement of the head is then controlled by the lead of the taps in the work. At a certain point, the direction of rotation of the taps is automatically reversed. After the taps have cleared themselves from the work, the operator throws in the quick return and head travels quickly up to the starting position and stops, the spindles being automatically reversed ready for the next operation.

A feature of this machine is the ease of operation. It is equipped with a quick approach and return of the head operated by means of friction clutches in the feed gear box. The operator is thus permitted, by means of a conveniently located lever, to raise or lower the head at a fast speed. The head can come down at this fast speed until the drills come in contact with work, no care being necessary to prevent damage, since when the drills strike the work the friction clutches immediately slip. The power feed is then thrown in, and upon completion of the drilling operation the head automatically returns at fast speed and stops at the starting position. This quick approach and return feature is not an attachment but is built integrally in all machines of this model.

Roller bearings are used for shafts and ball thrust bearings wherever required. All driving gears are of steel and the machine throughout embodies the best materials and workmanship. The drill requires a floor space 3 ft. by 8 ft., 10 in. Extreme height 12 ft., 3 in. Maximum distance between spindles and table 45 in., minimum distance 20 in. Traverse of head 25 in. Drill requires 15 to 20 h.p. It is manufactured by the Baush Machine Tool Co., Springfield, Mass.

BENCH-TYPE MARKING MACHINE

A bench-type marking machine capable of marking four lines of 11.16 in. lettering on flat or cylindrical articles up to 2 in. dia. has recently been placed on the market. The marking is done by means of cylindrical steel marking dies. When working on flat articles the die rolls over the work, while on round pieces both the work and the die revolve. The pressure is applied from the top by a cam movement operated through rack and pinion. The slide is fitted with roller bearings and the table can be elevated by a hand wheel by steps of thousandths of an inch, and locked in position, thus permitting control of the depth of marking. It is possible to mark articles at the rate of 700 pieces an hour. The machine requires a bench space 10 x 12 in. and weighs about 60 lbs. It is made by the Noble and Westbrook Mfg. Co., Hartford, Conn.

Guiding Business By Facts

FACTS AND figures in business are essential to sound judgment. They are a guide in intelligent buying and they contribute to efficient selling. When properly used, they give to employees a better viewpoint and in that way make for more effective co-operation.

These points were emphasized in a talk to business paper editors by the head of a large manufacturing concern who has been a close student of cycles as revealed by the actual history of his company, and who has built up an advisory staff whose functioning has been based largely upon a systematic application of facts and figures as revealed by practical operation of the business. It was pointed out as an example, that, in an investigation of selling, forty per cent. of his actual time was consumed by the salesman in traveling, that something like fifteen per cent. was wasted in waiting to see the prospect, and that only fifteen per cent. was consumed in selling. This information was of value, not as a basis of criticism of the salesman, but as assisting in readjustments of territory whereby the salesman might work with greater advantage to himself and to the company employing him. The same use of facts and figures was applied in connection with the advisability of buying new equipment and in many other departments of activity. Not the least interesting feature was the gradual development of a system of charts which showed, at a glance, the movements or cycles that could, to large extent be relied upon as assisting judgment.

Some criticism has developed because of the apparent overstressing of the cyclical theory as applied to business. It is pointed out that serious depressions have been brought about because of propaganda which sought to establish recognition of the idea that, because business has been good therefore it must follow that a period of depressions will succeed within a certain period. This so-called fatalistic assumption, it is claimed, had caused a lot of trouble in the industrial world. The speaker, on the occasion referred to, claimed that he was no advocate of blind submission of cyclical recurrence, but maintained that the application of absolute facts to business might discourage the growth of abnormal buying orgies as occurred in 1920, and make for procedure along more rational lines.

Every industry is productive of statistics. These are of greatest importance to those directly engaged in it. Secondly they have a relative bearing upon other industries. This is strikingly so of basic enterprises such as steel, mining and lumbering. It is here that the statistical expert finds much material for deduction and for evidence of cyclical movement. This information is a great aid to judgment on many matters, but it is a question whether they are reliable as to operations of cause and effect within specific time limits.

Reader Interest is Essential

WHEN John Wanamaker, some years ago, withdrew his advertising from free-distribution mediums, it was because these had no fundamental reader interest. This was the finding after a deep study of the subject. It was the conviction that the man who subscribed for a newspaper or other publication, expected to find advertising in it and valued that advertising as in the light of an investment, as something he had appreciated sufficiently to pay for.

The opposite was the effect of the free-distributed product. Here the receiver had no primary interest in the publication; it appeared in unexpected places, without request, and had somewhat the status of an unexpected guest.

Then, as now, free-circulation mediums were found to recognize no responsibilities toward the problems attending the business or industry, offered no constructive service through their columns, had no means of developing helpful discussion, offered no interchange of news or views, and in short had no interest beyond that contained in their advertising pages and the revenue they represented.

Car Shortage Holds Up Industry

IN A RECENT discussion, in which word pictures of basic industries were featured, it developed that all of these had experienced marked improvement during the past six months, with the exception of shipbuilding, but that inadequate transportation facilities were acting as a serious handicap to the full development of prosperity. Steel ingot production, it was pointed out, was on a basis 70 per cent. and had shown a strong recovery from strike influences. Lumbering, mining, automotive, electrical and textile industries had shown good growth, but all of these were held back by what appeared to be chronic traffic congestions and car shortages.

These reports form a composite picture with agreeable foreground but with disconcerting perspective. It is the result of influences which have retarded railway expansion, and much of this has been due to government regulation. This is not so strikingly true of Canadian as of American roads, but the congestion of traffic across the line to-day is certainly such as to point a moral. Reduction and restriction of net return has driven away new capital. Up to the present time this year, the roads have not even earned the 5¾ per cent. to which the Interstate Commerce Commission claim they are entitled. Not long after they do earn it, there will be another call for rate reduction. It is a case where, in contending that low rates are the chief consideration, the public is inclined to lose sight of the essentials of service in relation to industrial requirements.

October Best Month in Two Years Say Steel Men

Prices Firm, Orders Showing Larger Bulk—Market Has Better Supply of Galvanized Sheets—Deliveries From American Centres Poor—Pittsburgh Reports Dullness—Inflation May Cause Depression—Pig Iron Easier

ADVANCE PREDICTED IN WROUGHT STEEL PIPE

PITTSBURGH reports a dull fortnight in the finished steel markets. Toronto and Montreal jobbers state that October, to the present time, has been the best month in two years, with prices firm and orders showing a larger bulk than was the case in the more reticent period of early summer.

Shortage of cars is an acute problem at the producing centres on the other side, but this fact cannot explain a falling-off in orders for extended delivery. This is due largely to existence of stocks. There are sufficient cars to prevent further accumulations, but hardly enough to move what steel has been piled up. While general conditions, therefore, have not been favorable to price changes, makers of wrought steel pipe have sprung a surprise by advancing prices $4 a net ton. Eighth-inch merchant pipe is advanced 2½ points, or $5 the ton. This is said to be the first important price advance that the Steel Corporation has made in six years that had not first been made by independent producers. While no announcement has been made by Canadian pipe mills, there is some likelihood that Canadian prices will be revised. Advances made some weeks ago, it is said, were overdue. Material has increased in price since then, and it has been an expensive process to obtain supplies of skelp.

This advance in tubular goods is the only important price movement of the week in American markets. Canadian mills and dealers report little change. Owing to partial lifting of embargo, fair supplies of galvanized sheets are now available, and prices are quoted $6.60 to $6.75. In ingot metals, tin is active and an advance of a cent is announced by Montreal dealers. Old Country advices indicate the upward move in tin is due largely to speculation and not indicative of market buying movement.

Reduction in domestic pig iron prices $3 a ton to $36.30, has brought out some business. Pittsburgh reports a decline in pig iron, but that the process will be gradual. Foundry iron, selling at $32.50 a week ago, has sold in small lots at $30. It is predicted that pig iron will, by January, land eventually at $22 and $25, Pittsburgh. At present there is practically no inquiry in that market.

Advices from American centres indicate that there are those who believe that the period of great activity on the other side is to be followed by one of industrial depression; that this is the nautral reaction necessary to correct inflated conditions. The belief seems to be gaining ground that this reaction may be expected within very few months. General trade outlooks do not seem as favorable as in July. New enterprises, it is said, are somewhat discouraged and cost of labor, the standards set by the victory of striking miners, are said to have an influence toward conservative tendency. There has been no decline in steel prices, but premiums for early shipment are disappearing, and basic prices, while showing strength at present, may yield before the new year. Steel ingot production is now on a basis of 70 per cent. of capacity, double the average rate of 1921, and 20 per cent. higher than 1912 and 1913.

Toronto

October 25

THAT October will make the best showing of any month in the past two years, is the opinion of jobbers in the iron and steel business. September was shaping up well until war clouds began to gather, when there was a decided falling off, or a pause, until definite solution emerged in the Near East situation. Since then, business has shown strength. That there may be a slowing up in certain seasonal work does not seem to be viewed with alarm, for there is always seasonal work, whether it be winter or summer, and in many lines it is anticipated that the demand will continue. Deliveries from American mills are still difficult, but stocks in hand are sufficient to take care of immediate demand. Urgent call on import steel is, of course, handicapped by the shipping problem, but it is expected that requirements will be met in time to save the situation.

Iron and Steel.—Demand for merchant bars reveals orders of better size than in the hand-to-mouth process of the early summer. It is evidently felt that actual possession is a greater advantage than any remote prospect of price decline. The mill price $2.65 remains unchanged and warehouses are still quoting $3.25 to $3.40. Some reports indicate lower figures, say $3.15, but this is by no means an evidence that prices are softening or that revisions may be made shortly. It is attributed to competition which is particularly keen in this market, and to the lack of any stabilizing organization or influence.

In galvanized sheets, the market is said to have better tonnage owing to partial lifting of embargoes which permitted some deferred shipments to come through. The demand is strong and jobbers quote on a range of $6.60 to $6.75.

Boiler tubes are active. Prices are firm, but an advance of 5% by the mills, does not, as yet, seem to have affected jobbers' quotations. Prices follow:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 25	3 40
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 50
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28		6 60

Old Materials.—Dealers report inactivity, with neither furnaces nor foundries featured, to any extent, in the buying and with very little offering. The report received in this market, that Montreal was paying $25 per gross ton for No. 1, machine cast iron, was not taken seriously by large dealers. While not denying that the figure may have been paid in a very special case, they rather incline to the opinion that $21.50 was nearer a level buying price. They say there is very little prospect of radical change in Toronto prices at the present time. Dealers' buying prices follow:

Copper, light	9 00
Copper, crucible	12 00
Copper, heavy	12 50
Copper wire	11 50
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00

Pig Iron.—Recent reduction of domestic pig $3 per ton to $36.30 is reported to have loosened up a fair amount of business, but there is still evident a feeling that better prices are approaching, due to supplies that are accumulating in American markets. These, however, are not being moved, and it requires money to carry any considerable amount. Pittsburgh reports reductions, but at that, no great market has developed, and buyers display an impression that lower

levels must be reached before there is marked activity. Considerable Scotch and English pig is making its appearance, but it is considered doubtful if this can hold as American and domestic furnaces get back to normal conditions, and prices ease still further. It is not likely that the Steel Company will blow in its furnaces on foundry pig iron until after the first of the year. They now have one furnace operating on basic pig for their own steel requirements.

It may be interesting to Canadian pig iron buyers to learn that in spite of their imposition of 75 cents a ton on pig iron, large quantities of English pig are still going into the United States. Something like 31,119 tons came from one district alone last month, and shipments are still going forward on a large scale in spite of improved American production. English furnace authorities say that business from this continent, together with enlarging enquiry from other countries is absorbing their output and leading to scarcity on the English market. Additional furnaces will have to be lighted and production increased.

"In exports of both pig iron and steel," states The London Syren, "we are doing more trade than any country, though we are still a long way from the limits of our capacity. America is handicapped by tremendous transport distances and her home demand is always near to her output. The dollar premium, must, further, stand in the way of exports whilst the United States pursues her present policy. The world's steel and engineering requirements were never so great as they are now, and never within modern times was there so little foreign competition for the business."

Further advance in wrought steel pipe is predicted. American mills announce a reduction of 2 points in their discounts, each point meaning an increase of about $2 per ton. Eighth-inch merchant pipe was advanced in price 2½ points or $5.00 a ton. The demand for pipes has been abnormal, owing to activity in the building industry, and some mills are reported to be eight weeks behind in orders. Owing to the fact that the United States has differences in climate by which building operations may be continued in some sections all year round, the demand there has more stability, while in Canada, winter enforces a slowing-up process.

Non-Ferrous Metals.—Although foundries and galvanizing plants are fairly busy, nothing of any size is coming through in this department. Tin has shown remarkable firmness during the past week, due almost entirely, it is said, to manipulative factors in the Old Country and that, therefore, buying is showing a conservative tendency. Copper remains quiet. Current prices:

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	37 00
Antimony	8 50
Spelter	8 75
Antimony	8 50
Aluminum	22 00

Montreal

October 25

DEMAND continues good in all lines and October will show up as one of the best months of this year. Steel plates and boiler tubes have been particularly well to the fore lately and stocks are at present quite reduced. The delay in securing new tonnage from the mills is considerable and there may possibly be a shortage of these commodities in the near future. Shafting is due for an increase soon owing to the mills having advanced the price by 25c per 100 lbs. and this in due course will be put into effect by the jobbers.

Galvanized and Black Sheets.—The situation is much easier than it has been all summer, in regard to supplies, which condition has been brought about by a softening in the demand and increased quantities arriving from Old Country mills. Prices are continuing steady, however, and no change is anticipated. In fact, the replace value of galvanized sheets has considerably advanced, due to the recent increase in the value of spelter. Therefore, any weakening of the market price which should naturally follow, owing to the increased supplies available now, will not happen owing to the action of the spelter market. Current prices:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	3 40
Sheets, black, No. 28	4 40
Sheets, blue, ann., No. 10	4 00
Canada plates, dull, 52 sheets	5 50
Canada Plates, all bright	7 00
Galvanized Sheets, No. 28	6 50

Pig Iron.—There has been no change in either the pig iron or steel situation here during the past week, other than that No. 1 machine cast iron has become scarce, and it is said as high as $25 00 per ton has been paid. The situation in the United States is easing somewhat, and premiums for prompt delivery are becoming almost obsolete. Certain producers are accepting lower prices for their products than has been the case during the past two or three months. Pig iron has also shown some reductions, more particularly in Buffalo, Pittsburgh and the Valley.

The demand for pig iron in Montreal seems to show slight improvement, more particularly on the part of smaller users, but these are being cared for by imported English and Scotch brands which continue to sell below the equivalent of Canadian-made products. Notwithstanding this contention, it is stated that importers of English and Scotch iron do not contemplate putting in any considerable stock for winter use, because of the downward trend of the American and Canadian markets which might go to such an extent as to make it difficult for importers to sell their stocks at profit. Current prices:

Algoma, No. 1, car lots on tracks, nominal quotation		38 65
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	40 50	....

Old Material.—Some scarcity has developed in the more active departments. No. 1 machine cast iron, for example, went to high levels during the week. It is stated that $25 was paid. Available supplies seem to be somewhat limited. Advices from American centres indicate a feeling that prices are at high level and some material is coming into the market that was held by speculators who had hoped for further advances. Dealers' buying prices:

Copper, light per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	25 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Non-Ferrous Metals.—Tin markets have developed strength during the week. London reports that prices have touched new high levels almost every day, but the upswing is said to be the result purely of professional manipulation. Those likely to be affected by this are stepping slowly and cautiously for fear of setback. London reports that American consumers have not been large purchasers of late. Montreal jobbers are quoting tin at $37.50, an advance of one cent in the week, while spelter has advanced a quarter. On the other hand coppers are quoted a quarter easier. Current prices:

Lake Copper	17 50
Electrolytic Copper	17 25
Castings, Copper	17 00
Tin	37 50
Lead	7 25
Spelter	9 25
Antimony	7 25
Aluminum	22 00

Pittsburgh

October 25, 1922

THE PAST two weeks have been the dullest the finished steel markets have seen this year. Buying for far forward or extended delivery dwindled to small proportions before the end of September, but there remained a fair volume of activity in the prompt market, that activity having now disappeared likewise.

Production of steel ingots continues at a rate of about 36,000,000 or 37,000,000 tons a year, or say 70 per cent. of capacity, and approximately equal to the rate in June and July, while it is nearly double the average rate in 1921, and is 20 per cent. above the rate in 1912 and

1914, the two biggest tonnage years before the war.

Shipments of steel are approximately equal to production. Car shortages continue. Car supplies are not so light as to cause additional steel to accumulate, and not so heavy as to allow the steel previously accumulated to be shipped. A little headway has been made in this matter.

Tubular Goods Advance

Under date of October 19, the National Tube Company (Steel Corporation) advanced its prices on all welded tubular goods two points, or approximately $4 a net ton, with the single exception that ⅛ inch merchant pipe was advanced 2½ points. The basing discount on merchant pipe changes from 68 to 66 per cent. The advance includes line pipe, O. D. pipe and oil country goods generally, also steel boiler tubes.

The advance came as a complete surprise to the trade. No particular expectation had been entertained that any price action would occur at this time. It is substantially accurate to say that this is the first important price advance the Steel Corporation has made in six years that had not first been made by independents. In 1920, the corporation refrained entirely from following independent advances, while in the advancing movement that began last March, it has trailed behind independents. In some quarters it is suggested that this divergence from the usual policy may be due to the corporation expecting a period to begin soon in which prices will be under pressure, so that it is well to make an advance when it can be made, and allow more leeway for the market to decline in future. The independents, of course, follow the advance just made.

Except for this incident in tubular goods, prices of steel products for far-forward deliveries are entirely unchanged. Delivery premiums that have been ruling in bars, plates and sheets are decreasing farther. One can get quite early delivery of bars at 2.15c, against 2.25c recently, of plates at 2.25c or less, against 2.50c a month ago, and of sheets at 3.60c against 3.75c. For delivery at mill convenience bars, shapes and plates are 2.00c. Independents are not going below 3.50c on sheets and can make moderately early deliveries at that figure. The Steel Corporation's price is 3.35c but this is nominal since the corporation is sold out until it opens its books for the new year.

Good Stocks on Hand

The extreme dulness in the finished steel market does not indicate that consumption has decreased. Rather it represents the natural reaction due to buyers having been particularly free in their purchases all this year, presumably under the stimulus of the coal strike and the expected transportation disability. The coal strike was expected to be the greatest in the history of the coal industry and it was, but it caused only a slight decrease in steel production, and that only for a few weeks. It was not until after July 15 that steel production decreased to the rate that obtained April 1, when the coal strike started.

For months, it was impossible to believe that steel was being consumed at the full rate in which it was being bought and delivered, and the present stagnation in the market is, therefore, naturally to be attributed to the existence of stocks and not to consumption having decreased. Very likely consumption will increase in the next three months in the usual seasonal way.

Expect Period of Depression

As to the more distant future, the general trade prognostications are not nearly as favorable as they were in July. Ever since the notable victory of the striking coal miners over the operators and the general public, there has been a strong contingent arguing that there was inflation which would discourage new enterprise and would be followed by a general and important industrial depression when the course of inflation had been fully run. Generally speaking, this opinion has been almost universal, but this consensus did not mean a great deal on account of the widely different times various observers assigned for the duration of the inflation. Just now, the upper hand seems to be held by those who expect reaction in a very few months. There is difference of opinion as to how long the reactionary conditions will continue, but not much difference, because there is a remarkable hesitancy on the part of most men to form any definite opinion at all on this point.

As to the particular item of steel prices, the remaining premiums for prompt or early shipment will in all probability disappear in a very few weeks. Eventually basic prices, for extended delivery, will yield, but it is an open question how soon, whether within a few weeks, or not until the new year. Much depends on the size of order books of some of the independent mills. Some other independents have fair sized order books, while the Steel Corporation is well booked up. Some mills may soon reach the point of being unable to continue operating at the present rate on their old orders and then the question will be whether to protect the remaining orders on books or cut prices to secure new business.

Coke and Pigs Easier

Last week's report noted the first break in Connellsville coke prices, furnace coke having declined from $12 to $10.50. It has now declined to $8.00. This is still an altogether unreasonably high price. Even if the $8.00 average price that was seen in January and February was below cost of production, it was no more than a fraction of a dollar below, and the entire production cost was not in wages. The wage scale has been increased by somewhat over 40 per cent.

Pig iron, which began softening recently, is now definitely declining, but it shows no haste in seeking a reasonable level. Basic pig iron, which was offered a week ago at $30, valley, has since commanded that figure in actual purchase of some size. Foundry iron, which was available a week ago at $32.50, has sold in several small lots at $30. Bessemer remains at an asking price of $33. There is practically no inquiry in the market, which means of course that prices will recede slowly unless some furnaceman injudiciously undertakes to make a drive to build up an order book. In a soft market it requires actual demand to put prices down. Pig iron was about $19 for basic and foundry and $19 for Bessemer last January and February, when coke was $3.00. Since then freight rates on raw materials have been reduced, while wages at blast furnaces have gone up 20 per cent. Pig iron will probably land eventually at between $22 and $25 but it may take until January or later to get there.

MACHINE TOOLS FOR CANADIAN NATIONAL

Canadian National Railways, in addition to considerable purchases of machine tools and other equipment for St. Malo and Moncton Shops, have purchased for their western lines the following:—

1—36 in. Bertram heavy vertical drilling machine.

1—51 in. Bertram vertical standard Boring and turning mill.

1—Pond Type re-built engine lathe.

4—Canada Machinery Corporation lathes 24 x 44.

1—Alfred Herbert No. 4 capstan turret lathe.

1—Hammett radius link grinder.

2—Southwark hydraulic spring testing machines capacity 35 tons.

1—Model "E" power driven pipe bending machine.

1—Underwood portable crank pin turning machine.

3—Pipe cutting and threading machines

1—Kearney and Trecker No. 3 Universal milling machine.

Steps may be taken shortly to modify the existing regulations of the American Interstate Commerce Commission, which now requires all open-top cars to be loaded with coal when traveling away from the mines. Manufacturers are complaining of the shortage in this respect and as the bituminous coal situation has been greatly relieved it is felt that many cars of this type might be diverted to meet the needs of other industries. The handling of the Western crops has created a pronounced car shortage both in Canada and the United States and the increasing requirements for rolling stock at this time of the year makes the possibility of embargoes on many roads only a question of time unless some measure of relief is given the car situation.

News From the Industrial Field

B. F. Sturtevant Co. of Canada have recently increased their capital stock from $50,000 to $200,000.

Sudbury.—The sale of 500,000 acres of timber lands to a Philadelphia syndicate by the Algoma Central Railway is announced. The timber limits are along the Algoma line between Oba and Hearst, and it is said that the purchasers intend to erect a large pulp and paper mill on the property.

Calgary, Alta.—With oil developments in Northern Montana now being undertaken on a wide scale, various American companies are taking steps to secure extensive leases on the Canadian side of the line. One concern has obtained 31,000 acres in Southern Alberta, and others are considering the leasing of such substantial acreages.

New Process Gear unit of the Willys Corporation at Syracuse, N. Y., is in the market. Recently a sale was made for $1,904,000 to T. W. Warner, vice-president of Durant Motors, Inc., but this was subsequently unconfirmed. Several new bidders, one the Dana Syndicate and another representing Baltimore capitalists, have appeared. The plant is one of the finest in New York state and was employed in production of motor car gears.

Levis, Que.—The Levis-St. Lambert Highway, which will be the second national highway directly connecting Quebec to Montreal, will be completed next fall. The length of the road will be about 180 miles, and over 90 miles are now partially completed. The cost o the road will be over $1,500,000, compared to over $3,000,000 for the Quebec-Montreal highway. The Quebec section of the road has nearly 40 miles completed, while the section, Levis to St. Antoine de Tilly, Lotbiniere, has now been finished.

By the close of the shipping season, the British Empire Steel Corporation will have shipped 700,000 tons of iron ore to Germany and established a market with the large steel plants there. Two blast furnaces are being operated and as soon as the St. Lawrence season closes, a third will be blown in. A moderate amount of export steel business has developed in addition to an improved domestic trade, and it is likely that railway demand for cars and other material will further contribute to the activity of the industry. According to the president, Roy Wolvin, the first half of the year was unsatisfactory, due to conditions in the steel industry, but general conditions had greatly improved.

J. B. Foote, of Foote Bros. Gear and Machine Co. of Chicago, died suddenly last week.

Byron Lederer, president of the Birmingham Motors, Peterboro, Ont., died suddenly from an acute attack of heart failure while staying at the King Edward Hotel, Toronto, early this week. Mr. Lederer was 50 years of age, single, and came from Brooklyn, N. Y., to preside over the Canadian activities of the Birmingham Motors.

Windsor, Ont.—A plant for the manufacture of liquid chlorine is at the present under construction by the Canadian Salt Company. It will have a capacity of ten tons a day. This is the first plant of its kind to be erected in Canada. The Company is also making additions to its evaporator plant and has installed fuel economizers in their boiler room.

Edmonton, Alta.—The Provincial Government announces that American capital has been secured to open and develop the Butterfield iron ore deposits discovered about a year ago on the shores of Lake Athabasca. If iron ore is found in Alberta in large quantities, this, together with the proximity of coal, would presage a steel industry for the future.

Quebec, Que.—Timber cutting in the province of Quebec this fall will return to the normal average of the last ten years, which was 1,000,000,000 feet, according to a statement made by the Hon. Honore Mercier, Minister of Lands and Forests of the Provincial Government. It was explained in this connection that there have been years in the period when the cutting was higher but the figure mentioned is considered the normal one.

Montreal, Que.—Various reasons are quoted for the fact that the American dollar has been at a discount in Canada, but the one which is mostly attributable, according to banking officials and financiers, is general prosperity in Canada. It was thought that the market had been engineered and the American dollar forced below par, but this is refuted by exchange brokers as being an impossibility, owing to the strength of the American banks. It is also said that the new American tariff might have something to do with the exchange. The present grain movements and huge tourist traffic have a bearing on the fluctuations of the American exchange as also has the Canadian borrowings in New York.

Montreal.—Large cargoes of incoming coal and outgoing grain are combining to bring an unusual number of ships to Montreal over seventy sea-going vessels in port on September 7, 1921, and it is probable that the latter figure will be exceeded. Many steamers commence to load grain practically as soon as their coal cargoes are discharged, and to facilitate the grain movement, local elevators are being operated at full speed, night and day.

Port Arthur, Ont.—Announcement has been made of the purchase of 66,500 acres of timber and surface rights on Isle Royale from the Island Copper Company by the Minnesota Forests Products Company of Duluth. It is stated that development work will commence at once, the Island Copper Company to work the copper properties and the Minnesota Company to take the timber. There is a large quantity of pulpwood, cedar, birch and maple, the latter being of excellent quality, and which may be used for veneer.

Edmonton, Alta.—The Northwest Lumber Company's big mill has closed down after competing a cut of about 15,000,000 board feet, and the D. R. Fraser plant, which is still running, will add 5,000,000 feet to the Edmonton output. Some of the smaller mills in the Lesser Slave Lake district have also had a good season. There is a good demand for Alberta spruce this year, particularly from the United States, where it has the reputation of being more easily handled and freer from knots than the mountain spruce.

Dr. A. C. Humphries, Stevens Institute of Technology, Hoboken, N. J., president of the American Institute of Consulting Engineers, will be the principal speaker at the dinner in connection with the fourth annual meeting of the University of Toronto Engineering Alumni Association, Oct. 27 and 28. The annual meeting will be held in Room 22, Chemistry and Mining Building, Oct. 28 and the annual re-union dinner, Convocation Hall (rear,) Saturday evening.

In an American bleachery plant, recognizing the equal partnership idea as between capital and labor as an experiment, the $1,250,000 capital is assumed by the 600 employees, and every penny of profit is shared according to the investment of each. Managerial control is distributed in the same way. As a result, there have been no strikes, increased production, lower overhead, negligible labor turnover, smaller loss through carelessness and lessening of labor monotony.

That Sir Henry Thornton, new head of Canadian National Railways, is leaving England on the best of terms with labor is evident from the fact that, in connection with functions marking his departure, leaders of railway trades unions have arranged for a large farewell gathering.

Lackawanna Tubes Limited, Welland, which took over the plant of the Welland Machine and Foundries, and proposed installing a plant to make boiler tubes, has been making slow progress toward operation. The men behind this organization are said to represent large Pittsburgh interests.

Welland.—Welland Packing Company with capital of $100,000, has purchased a site in Crowland Township and has started the erection of a packing plant. The machinery for this new industry has already arrived and it is expected that the plant will be in operation early in December.

The self-oiling feature can be enhanced in the case of bearings operating under unusually severe conditions by adding a small quantity of finely divided graphite to the lubricant. The graphite, of course, mixes with the oil in the pockets of the metal and provides a most efficient self-lubricating surface.

St. John, N. B.—In order to increase the capacity of its mill here from 60 to 80 tons of sulphite pulp a day, the Nashwaak Pulp and Paper Company is reconstructing practically every department. New improvements include a boiler system, Jenssen acid system, new screens and modern improvements to their drying system.

Lubrication of worm gear drives is most essential for resisting wear. Abrasion is generally due to over-heating, and this condition can be avoided by running the worm in a bath of oil. The oil not only carries away the heat, but likewise forms a film on the threads and teeth which actually prevents the two metallic surfaces coming into direct contact.

Employees of the Works Department, Dominion Government, claim to have grievances which they have drafted into resolution form, as a step toward protest to Ottawa. They want redress in the matter of salary, claiming that it should be stabilized to include the bonus now allowed and that employees with private incomes equal to their wages, should be asked to resign.

The function of bearing metal is solely to prevent, or minimize damage due to failure of lubrication. Under normal conditions the babbitt has little, if any, influence on the operation of a machine and its virtues become apparent only when lubrication is suspended. Its value is, therefore, in direct ratio to its ability to eliminate, or reduce, the wear or damage which follows a suspension of lubrication. Any other standard of value is meaningless.

British Columbia Industries Active; Iron and Steel Project Up to Ottawa

VICTORIA, B. C.—Interests behind British Columbia's new $15,000,000 iron and steel project now declare that it is for the Ottawa Government to say whether or not the plan shall become a reality. The Provincial Government has agreed to guarantee one-third of the bonds issued provided that the Federal and Imperial Government do likewise.

Advices have been received from the British Board of Trade, indicating that it will support the proposition under certain conditions, one of them being that the Ottawa administration stand back of it. It asks as one of the conditions on which it will support the bonds of the company that its investment be spent in Great Britain in the purchase of plant and equipment, and it also requests that its financial advances be considered as a first lien on the assets of the plant.

Meanwhile there has been speculation as to the location of the proposed steel mills. Kamloops, an important railway centre in the interior of the province, is being considered. Vancouver, because of its proximity to rail terminals and the fact that the city is the manufacturing metropolis of the province, has certain advantages. Vancouver Island, on account of its possession of huge deposits of coal and its proximity to iron and limestone deposits, is particularly favored. Statements have been made that Union Bay, a coal port on the east coast of Vancouver Island, has been selected as a site, but these are without confirmation.

Pulp and paper mills have maintained their usual output and they are now supplying California, and Orient and Australia as well as domestic markets. Two or three new mills are likely to be established in the near future. The largest of these is the Wigwam Pulp & Paper Company plant, which is to be built at Elko in the Kootenay district at a cost of about $13,000,000. The Prince Rupert Holding Company has been organized to take control of the Prince Rupert Pulp & Paper Company, which has been in financial difficulties and this is taken as an indication that a resumption of construction is contemplated. Hon. T. D. Pattullo, Minister of Lands, is now in Great Britain negotiating with financial interests with a view to having British capital invested in British Columbia timber and pulp mill enterprises.

General industrial conditions throughout British Columbia have shown improvement lately, and prospects are bright for a fairly active winter. The lumber business, which is regarded as an accurate barometer of general trade conditions in the province, is again on a firm footing and production has reached an exceptionally high level. Demand for lumber in the eastern provinces and states has been well sustained this season. As a result of the big crop on the prairies, Coast lumbermen expect to sell extensively to the prairie territory during the next few months. Unprecedented building activity in the East has absorbed all the lumber that can be shipped, although the grain movement and other factors have caused a rather serious shortage west of the Rocky Mountains This has resulted in the routing of more lumber than ever by way of the Panama Canal.

Owing to the high tariff fixed for nitrate soda shipped into the United States, the plant of the American Nitrogen Products Company at Lake Buntzen, near Vancouver, is being converted into a nitric acid plant. Between four and five million dollars may be invested in the plant extensions to be made, according to C. E. Graf, head of the organization. The plant has been equipped to take nitrogen from the air by electricity, being the only establishment its kind on the continent, with the exception of a small plant at La Grande, in the state of Washington.

British Columbia wholesalers and shippers are trying to induce Eastern Canadian manufacturers to make greater use of steamships in sending freight to British Columbia. They point out that on articles such as pianos, where time taken in delivery is not an essential factor, the freight rates by steamship are about one-fifth of the rail rate. A special advantage to British Columbia in the shipping of goods from the East via Panama Canal is that the system provides tonnage for the shipment of British Columbia products, such as lumber, to the Eastern markets. In the past, there has been plenty of cargo for the East, but not enough westbound to make it worth while for ship operators to send out their vessels.

The depressed state of the copper market has been a discouragement to heavy output of that metal, but production has been on a generally high standard notwithstanding, and the installation of new electrolytical processes at the plants of the Consolidated Company at Trail will result in important advances in zinc and lead yield this year. Silver is expected to reach a new peak and gold, largely as a result of the phenomenal success of the Premier in the Portland Canal district, will have one of the best years in history. Continued high cost of labor and machinery and lack of transportation facilities are deterrents to mining activity on the part of the small companies with limited capital, but the larger corporations are going ahead with their operations and are even carrying out important extensions

Any Machine You Want—From Stock
From our large stock of full lines of Iron and Woodworking Machinery, Boilers, Engines, Contractors' Machinery, Electric Motors, Saws, Shingle and Lathe Mill Machinery, etc. You may depend upon your order being shipped promptly and intelligently. DOES BETHLEHEM STEEL WANT BALDWIN PLANT?

THAT the Bethlehem Steel Corporation may establish a branch plant in Canada is the report current during the past few days in Toronto iron and steel market. No very definite information is available as to the extent of direct or indirect negotiations, but the Baldwin plant, now idle, has had persistent mention in that connection. Captain Hugh C. Paynter, president Baldwins Canadian Steel Corporation, when asked for a statement, declared that he had absolutely nothing to say and that he preferred not to discuss the matter in any shape or form. This still leaves the matter open to speculation.

The Baldwin plant, after about two years' operation in the production of tin plate and black sheets, closed down a few weeks ago. It was claimed that difficulties in securing shipment of materials, such as sheet bars, from the United States under present conditions, had much to do with the shut down. The Baldwin plant represents an investment of $4,000,000.

Increasing importance of the Canadian market is fully recognized by the large steel corporations of the United States. Notable evidence of this exists in the huge plant now being erected by the U. S. Steel Corporation at Ojibway near Windsor, Ont. This is said to be a duplicate, practically, of their Gary plant.

If the Bethlehem interests have a Canadian plant in view, they have undoubtedly satisfied themselves as to the possibilities here. In the production of black sheets they would have their own sources of supply in sheet bars and other essentials, and this would seem to ensure positive quality.

One difficulty, it is said, that has often beset industries of this kind, producing in one country, but buying materials in another country, is the fact that buyers and sellers of these materials have been competitors in the ultimate market. It is claimed that quality has, therefore, been too easily a matter of manipulation by interests in control of materials. Just to what extent this problem entered into the operations of the Baldwin plant, or whether it entered at all, cannot be ascertained. If it is a consideration, a self-contained, independent organization would be well-equipped to apply the remedy.

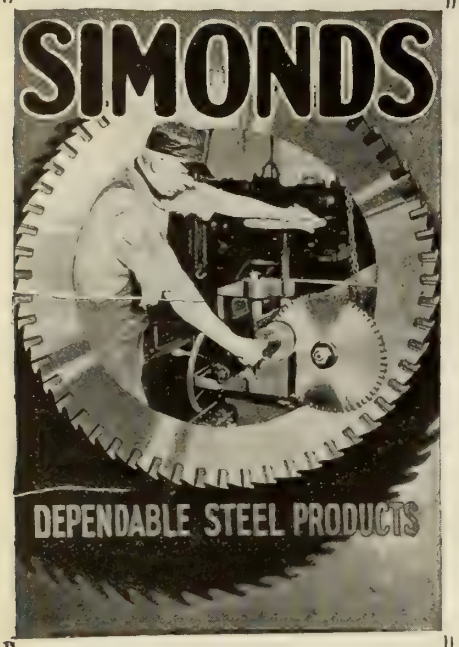
The Bethlehem Steel Corporation will spend immediately $15,000,000 on its newly acquired Lackawanna Steel Company plant in Buffalo. Eugene G. Grace, president of the corporation, made this announcement after a two days' inspection of the property. "Conditions of the steel industry have improved so rapidly in the last six months that there is to-day sufficient business to warrant 100 per cent. operation in all the Bethlehem Steel Company's plants, including the Lackawanna property," Mr. Grace said. "The problem of labor to operate the present local plant, and at the same time to make improvements and additions to the property, is a controlling factor."

Enquiry at the Toronto office of the United States Steel Products Co., who might be supposed to know something of proposed activities involving large steel interests, revealed no light on the rumored move by Bethlehem. The latter, with the recent passing out of the Consolidated Steel Corporation, ceased to have direct representation in Toronto.

A plant for manufacture of asbestos products, the first of its kind in Canada, is being erected at Asbestos, Que., to cost $100 000. At present the raw material is shipped out of the country and imported as a finished product.

About 1,800 men are working on the construction of the Welland ship canal. The approach of cold weather will necessitate shutting down on those sections where concrete work is being carried on.

The royalty on asbestos in the Province of Quebec has been reduced from $5.00 to $2.50 per ton. This concession was made at the request of a number of asbestos mine owners and others interested in the industry.



Inserted Tooth Metal Saws

Greater production and economy are reasons why Machine Shops are equipping their metal cutting machines with Simonds Inserted Tooth Saws. Fitted with High Speed Steel Teeth in an especially fine steel plate, these saws cut rapidly without dulling easily.

The Simonds "00" style Inserted Tooth metal saw cuts only 3/16 inch kerf.

BUSINESS PAPERS

(Continued from page 24)

time to time by periods of depression brought on by unskilful and inadequate use of financial facilities. Though crops might be good and business fair, a sudden tightening of money could precipitate hard times by interrupting the ordinary process of business.

With the advent of the Reserve Banks, and the creation of a reservoir out of which money could flow to meet sudden emergencies, American business was freed from this danger and assured at all times of sufficient liquid funds to transact its operations.

The Reserve System did not create new stores of gold or silver; it did not make money out of thin air, or change the fundamental laws of finance in a single particular It simply perfected, and improved our financial machinery.

Improve Industry's Mechanism

In similar manner the nation should strive to improve and perfect the mechanism of industry. There is no more excuse for over-buying or over-production than there was for money panics. Depression through over-production proceeds from lack of facilities for adapting production to the demands of the market. Depression through over-buying proceeds from lack of facilities for ascertaining the public's wants and from fear of a sudden halt in supplies.

The Department of Commerce, has already attacked the problem of providing a proper organization for bringing the manufacturer, the retailer and the public into closer touch. The effort thus begun should be encouraged and supported. It is not enough that statistics and estimates should be available; the business man must be trained to use them and to base his activities upon accurate knowledge of conditions rather than upon his own surmise of what those conditions are. Here is a field where the business papers can be of supreme usefulness to their readers, and to the nation.

TENSION AND WORKING STRAINS

(Continued from page 21)

slack strand 60 pounds in order to give the necessary 60 pounds of pulling power, and the bearing must stand a load of 180 pounds, just twice the load in the other case noted above.

The maximum load on the fastener in each case is the tension of the tight strand of the belt. In the extreme case of the poor belt described, the fastener would have to withstand 120 pounds per inch of width. Efficient belt hooks under many tests, have shown a strength never less than 400 pounds per inch of belt width and it is easy to understand why they carry the full belt load and do not put out. Even in a poor belt carrying its rated load (which as a matter of fact is not possible with such a poor belt) there is a margin of safety of 400-120 or 280 pounds.

In the chart the length of the bars represents the total strength of efficient belt lacing in a one-inch belt. The black area shows the proportion of this which is actually required to transmit the rated horse power to the belt, while the white area shows the margin of strength remaining as a safety factor.

C. G. E. PROTESTS TAX BILL

Further explanation of the attitude of protest by the Canadian General Electric Co., Toronto, with reference to their city assessment and of their inclination to move to a smaller centre is found in their appeal to the Court of Revision. The company has had a fixed assessment for 20 years of only $150,000. This arrangement expires with the present year. So the company will have to pay taxes on the present approximate values in 1923. Toronto assessors fix these at $349,621 for land, $685,000 for buildings, and $692,771 for business assessment. Instead of paying $10,000 a year as in the past, the company will now have to pay, provided the assessment is confirmed, about $66,000.

It is claimed by the company that the assessment is excessive and that, owing to commercial depression, the plants were not being operated to capacity and, consequently, the business could not stand the heavy increase. Counsel, in presenting the case for the company, to the court, said that it was employing about 1,200 men only now, but in normal times it would have 5,000 employees. He requested that the assessment be based on the present output of the plants. In reply to questions by the court, counsel said the company would be pleased to advise the Assessment Department when the plants were again operating at normal capacity. He maintained that he had made a reasonable request in asking for a reduction, and intimated that the business would not stand the heavy increase in taxation that must follow the confirmation of the new assessment. If no relief were granted, the management of the company would seriously consider the question of removing the entire plant from Toronto, possibly to Peterboro, or some other point, where it would be given reasonable assessment and moderate taxation.

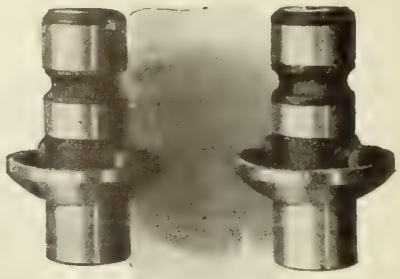
BENCH GRINDER WITH SKATE ATTACHMENT

The Prescott Emery Wheel Co., has recently brought out an attachment that may be fitted to their bench grinders, for the grinding of skates without removing them from the shoes. It is possible to slide the fixture along a smooth surface which assures a uniform grinding of the skate blade. The holder is so constructed that skates of any make can be successfully held and sharpened whether on or off the boot.

Canada Forge Co's. plant in Welland, which has been closed for the past two years, may resume operations shortly. Activity in locomotive and car construction would mean much to this industry.

Make a Turret Lathe of Your Engine Lathe

Jarvis Collets convert an engine lathe into a turret lathe by simply using one of the Jarvis Quick Change Chucks, which allows the use of any number of different tools.



Acquaint yourself now with Jarvis High Speed Tapping Devices and Quick Change Chucks and Collets.

The booklet will be a worthy addition to your Mechanical Library.

It is interesting—

It is free—

It is yours for the asking—

The Jarvis High Speed Tapping Device is superior to any other.

It has a ball drive and ball reverse, making easiest action, with no clinching or binding.

Reverse motion faster than the drive.

Specially designed Chucks make special taps unnecessary.

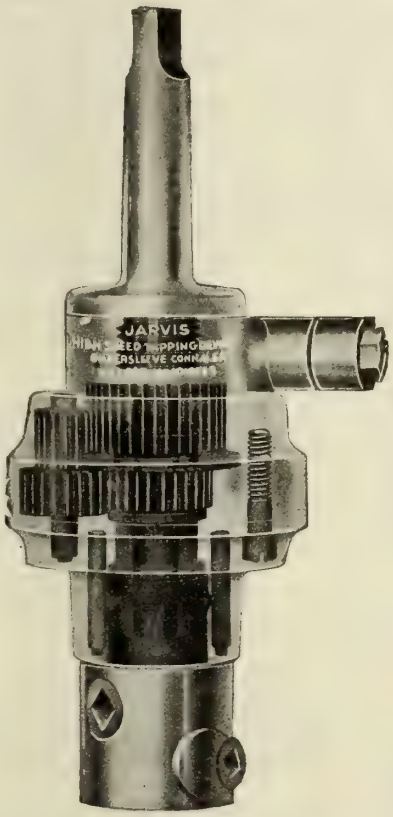
Tap breakage reduced to the minimum.

It makes no difference whether the tap is forced against the work in a Drilling Machine, or the piece is pushed towards the tap in a Speed Lathe.

Two Styles of Chucks.

Seven Sizes of Tappers.

Range of Tapping from 0 to 2 inches inclusive.



Jarvis Tappers and Quick Change Chucks

And collets are developed to such a degree of perfection that the Geometric Tool Company recommends and furnishes them as a fitting adjunct to their line of threading tools.

Where one hole is drilled, reamed, counterbored, tapped and a stud set, or any two of these operations are done with one spindle, the Jarvis Quick Change Chucks pay for themselves in a very short time. Changes are made without stopping the Drilling Machine or Lathe.

There is no burring from constant use to interfere with the easy entrance or operation of the Collet.

Jarvis Quick Change Chucks and Collets consist of a Chuck or locking member and a sufficient assortment of collets for any job.

Any standard Drill Chuck can be fitted to the Morse Taper Collets.

Combination Tapping Device and Quick Change Chuck

In place of the regular chuck, the Tapping Device is equipped with a Quick Change Chuck, forming a Combination Tapping Device and Quick Change Chuck. This is the combination much in demand.

The Booklet tells the Complete Story. ***Write Now.***

$5 May Save You $500 or $5,000!

You work hard for the dollars you save. Properly invested they can be made to work hard for you. But they must be properly invested.

If you feel the need of a guide to show you how to invest your money to bring you the biggest return consistent with safety; to show you how to avoid the pitfalls of investment; you need THE FINANCIAL POST.

It will give you a personalized investment service. Its articles every week will tell you what you want to know about investing. Its discussion of current business and national problems will give you a new angle on economic and political questions. You will have too all the privileges of the Investors Inquiries Department. You may ask as many questions as you like about your own investment and financial problems—the standing of your broker, and the analysis of particular securities, insurance problems, etc. This service is free to all readers.

Stop losing money on bad investments. Invest $5 now where it may save you $500 or $5,000. Pin a $5 bill to this ad. (or your letterhead), write your name and address and we will send you THE POST for one year (52 issues).

THE FINANCIAL POST 143 University Ave. Toronto

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BLACK & DECKER

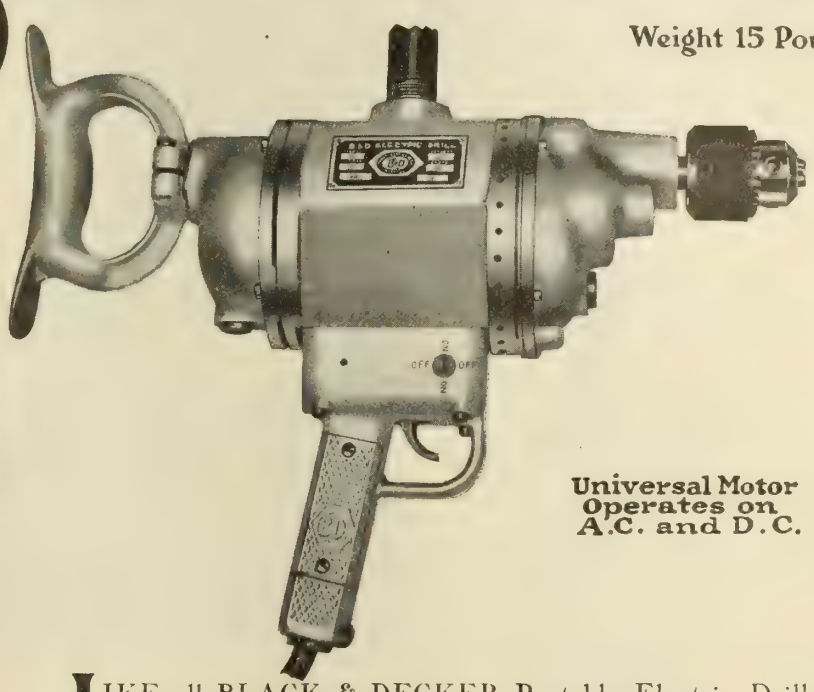
SPECIAL HALF-INCH DRILL

"With the Pistol Grip and Trigger Switch"

$106.00

1922 Model
1922 Price

Weight 15 Pounds



Universal Motor Operates on A.C. and D.C.

By removing two screws cover plate of switch handle may be lifted off, exposing terminal block to which electric cable and motor leads are attached by means of SCREW TERMINALS. Cable may be renewed quickly and easily without soldering.

A little thing which means a lot to the busy mechanic.

LIKE all BLACK & DECKER Portable Electric Drills this SPECIAL HALF-INCH DRILL is powerful, durable, comfortable to handle and perfectly controlled.

"The Pistol Grip and Trigger Switch" not only provides a large comfortable grip and instant control of the switch, but reduces the breakage of expensive drill bits, because the switch may be operated at critical times, such as when bit is breaking through the work, without disturbing the position of your hands. *"The Pistol Grip and Trigger Switch"* control is instinctive—practically automatic.

THE BLACK & DECKER SPECIAL HALF-INCH DRILL fits the BLACK & DECKER BENCH DRILL STAND, or POST DRILL STAND, and can be secured from your regular jobber.

SPECIFICATIONS

HOUSING—Aluminum Alloy.
MOTOR—Universal. Operates on Direct or Alternating Current.
AIR COOLED—Die Cast Aluminum Alloy fan keyed to armature shaft.
GEARS—Double Reduction, stub tooth, chrome nickel steel heat treated. Run in grease like an automobile transmission. (No brass gears are used on any Black & Decker tools).
CONTROL—*"With the Pistol Grip and Trigger Switch."* Improved switch handle with removable plate and screw terminals.
CHUCK—Three-jaw geared nut chuck for straight shank drills up to ½ inch.
NO LOAD SPEED—475 R. P. M.
NET WEIGHT—15 pounds.
EQUIPMENT—Drill is complete with 15 feet duplex electric cable, attachment plug, combination spade handle and breast plate, detachable side handle.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

A. J. HOPKINS, Manager

Miniature catalogue will be supplied on request.

From a British Engineer

A prominent British engineer brings to light some interesting data on the causes of hack saw breakage which closely parallels the experience of The L. S. Starrett Co. The following figures are based on conditions in four large works:

Causes of Hack Saw Breakage

Faulty blades.....	3.2%	Wrong blade for the job.....	17.3%
Gross carelessness on the part of the operator.....	29.4%	Wrong speed on stroke	21.6%
		Wrong pressure.....	28.5%

Ignorance or carelessness on the part of the user is responsible for most of the blade breakage. If each workman has a copy of the Starrett Hack Saw Chart (any number sent free on request) in in front of him—he can't go wrong on the blade to use for each different type of work.

And if those in charge of the shop thoroughly understand the use of hand and power hack saws, there will be mighty little breakage caused by wrong speed or pressure. "Hack Saws and their Use" covers the subject completely and is used as a reference in thousands of plants today. Every production manager and foreman should have this valuable work on the least understood tool in the shop. A copy will be sent free on request. At the same time ask for Catalogue No. 22 "3" and Supplement describing the new Starrett Tools.

Solving Boring Production Problems

WE SUPPLY THE WORLD WITH EXPANSION BORING TOOLS AND EXPANSION REAMERS

Davis

Expansion Boring Tools and Reamers

STYLE "V" TOOL

STYLE "E" TOOL
Pilot is Hardened and has Oil Grooves

THE POSSIBILITIES and advantages of Davis Expansion Boring Tools and Reamers in your boring operations are clearly indicated in their uniform, successful performance in those plants, where maximum efficiency is maintained—fully meeting all production demands, at a saving in costs of 25 per cent. to 50 per cent.

There is no guess work or uncertainty as to the results these tools will produce; their merit is recognized in thousands of shops where they have fully demonstrated their efficiency and adaptability.

Practical cutter expansion to compensate for wear or to bore any size within range of tool, is obtained by means of micrometer adjustment, graduated in .001—insuring absolute accuracy in boring or reaming any class of metal, at a guaranteed saving of 25 per cent. in costs.

The illustration shows some special types of boring tools maintaining maximum production in one of the largest plants in the country.

LET US HELP YOU
SOLVE YOUR OWN PRODUCTION PROBLEMS

With 19 years of constant effort devoted to the exclusive manufacture of boring and reaming equipment and with a competent staff of engineers, we are qualified in offering suggestions on boring and reaming equipment for any production requirements. Take advantage of our free engineering service and send in sketches of your work for our recommendations.

Our literature on Expansion Boring Tools and Reamers will interest you. Ask us to send bulletin No. 350 and R 532.

LARGEST EXCLUSIVE MANUFACTURERS OF EXPANSION BORING TOOLS AND EXPANSION REAMERS

Little Giant

NUTS, rods and pipes are frequently located in almost inaccessible places. When replacements are necessary the man without a "Little Giant" Pipe Wrench is sadly handicapped. The Little Giant grips and lets go quickly and surely, and with it a much greater turn can be accomplished.

In running pipe lines close to walls, ceilings or corners the labor cost is apt to be high. It can be lowered by using the LITTLE GIANT WRENCH. The jaw opening can be thrust on to the pipe, rod or nut as easily as a pair of pliers. It grips instantly, gives a far greater turn and requires less muscular effort by reason of the extra long handle.

There are but three drop forged hardened steel parts in the LITTLE GIANT. It has two to four times the service life due to extra sets of teeth.

Hundreds of users have written us enthusiastic letters concerning LITTLE GIANT performance. You'll add to their number once you see it in action.

Where they tap nuts by the ton

Records Are Kept of Tap Performance

These show that Pratt & Whitney Taps score highest on two counts. Time between resharpenings is longer than ordinary. They can be sharpened and resharpened and still retain their original size long after other taps have gone to the scrap pile.

The "Con-eccentric land," an exclusive Pratt & Whitney feature — coupled with superior workmanship and rigid inspection both of the steel and the taps — are the secret of their long life.

BLISS

Quality and Quantity Production

ALMOST the entire production of a large Western Screw Company is manufactured by the upset process. Heads for the variety of products are then trimmed by BLISS Presses. On the day the photograph was taken five girls, trimming hexagon heads on large bolts, secured these respective scores: 25,700, 25,300, 25,200, 24,100, 22,100.

This is another illustration of BLISS Presses successfully meeting the test of rapid, continuous, accurate production. BLISS Machinery is machinery plus knowledge and experience. It insures you economical production.

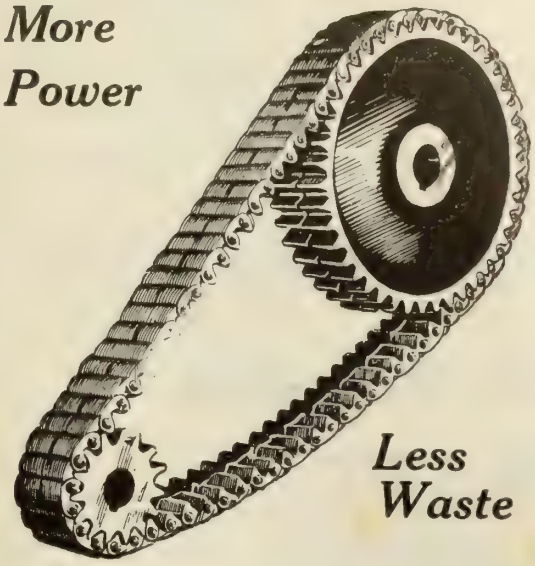
RENOLD
SILENT CHAIN DRIVE

More Power



Less Waste

The Recognized Standard for Efficient Power Transmission

Twenty-six years' highly efficient performance in the finest plants in the country has built up an enviable reputation for Renold Silent Chain Drives. Absolute reliability in service with maximum efficiency and minimum maintenance costs has made "Renold" the universal name for power transmission chains. Renold Silent Chain Drives are applicable to any powers, no matter how small or large and not only are they silent in operation, but also unaffected by heat, cold or moisture.

Let Renold Chains solve YOUR power transmission problems, and ensure YOU maximum efficiency, durability and service. Our engineering service is at your disposal without obligation. Why not write us?

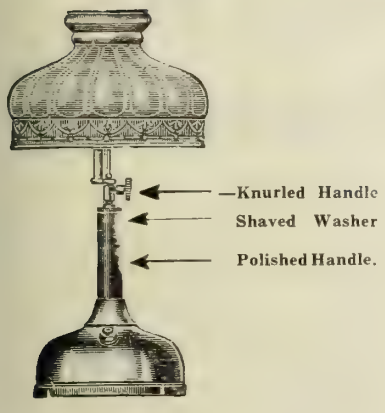
DIAMOND FIBRE

"The Best in Finish and Quality that we have ever had"



An outstanding instance of the wide range of uses to which Diamond Fibre can be put is provided by the Coleman Lamp Company of Toronto. It being imperative that only the best material procurable should be used in the manufacture of their lamps, they turned to Diamond Fibre as the material for the knurled and polished handles and shaved washers—important parts of their lamp construction. That their policy was justified is shown by the following extract from a letter they wrote us:

> "We wish to take this opportunity of thanking you for the prompt service that you have been giving us on our recent orders and for the splendid quality of fibre that you are supplying us for our factory. The tubes that you have furnished us are the best in finish and quality that we have ever had."

What holds true for this firm holds true for every other firm that deals with us. We give prompt attention to all orders and our wide experience in the uses of fibre is always at your command.

Many of your competitors have saved considerable expense annually by substituting Diamond Fibre for other material. Why not you? Is it not worth investigating?

Send for booklets on Diamond Fibre and Condensite Celoron. They are full of worth-while information.

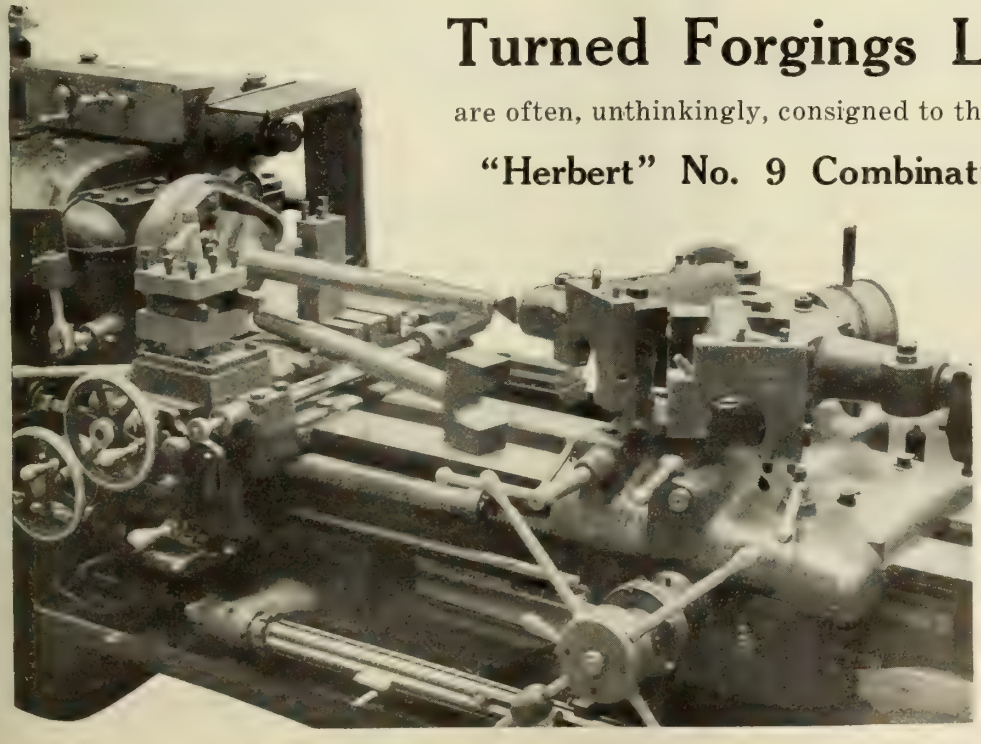
DIAMOND STATE FIBRE COMPANY of Canada, Limited

Toronto, Ontario

Turned Forgings Like These---

are often, unthinkingly, consigned to the Engine Lathe when the

"Herbert" No. 9 Combination Turret Lathe



will produce them even in quite small quantities much more economically. Here's a case in point. The piston rods shown are about 24″ long under the head, which is 7½″ across the corners. The long plain portion is 2⅛″ diameter and the machining time is 30 minutes.

Compare this with your present method of handling similar forgings and ask our specialist to call and advise you on your own work without obligation.

Big Jobs

HUNDREDS of repair jobs that formerly kept rolling stock idle for weeks, and even months, are now speedily, economically and permanently effected by the oxy-acetylene process.

Dominion Oxygen Service contributes largely to the facility by which these jobs are completed. A service that places an unlimited supply of Dominion Oxygen and Prest-O-Lite Dissolved Acetylene of uniformly high quality, in safe, easily-handled cylinders with leak-proof valves, in the shops where and when it is needed.

We would appreciate an opportunity of quoting prices and telling you about our facilities for giving unusually prompt service.

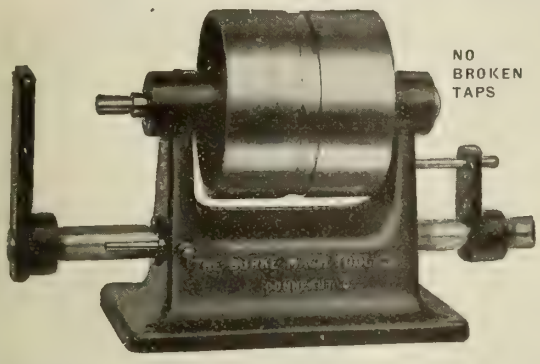
Repair Parts Are Practically Unknown



BURKE TAPPERS are simple to operate. It is not necessary to tie up the production of another and higher priced machine as when using a tapping attachment—they are complete in themselves. Production is limited only by the speed at which tap can be run and the ability of the operator to place the work on the machine. There are no parts to rapidly wear out, frictions are of gray iron and last indefinitely—in fact, repair parts are practically unknown.

720 Holes Every Hour-- Doesn't Worry This Youngster

Tapping ¼" open hearth steel couplings for a magnet drive with a ⅝"-18 thread isn't exactly child's play. There are 16 holes in each piece and, like all work of this class, it must be accurate. The boy shoves the work right along —one complete piece every 80 seconds—720 holes per hour.

He's using the

"PROCUNIER"

SAFETY TAPPING ATTACHMENT

the only device on the market having a balanced reversing mechanism, eliminating all side pull or torsion.

The Safety Friction allows the operator to run the tap right to the bottom and use the bottom of the hole for a stop, without fear of tap breakage. **The reverse speed is twice that of the forward.**

If you've tapping to do get the details of the Procunier line. Learn the working value of our **Tapping Attachments, Tap Holders and the** popular Procunier Patented "Double Jaw" Chuck which drives the tap by the square and true by the round. Let us show you how they reduce production costs.

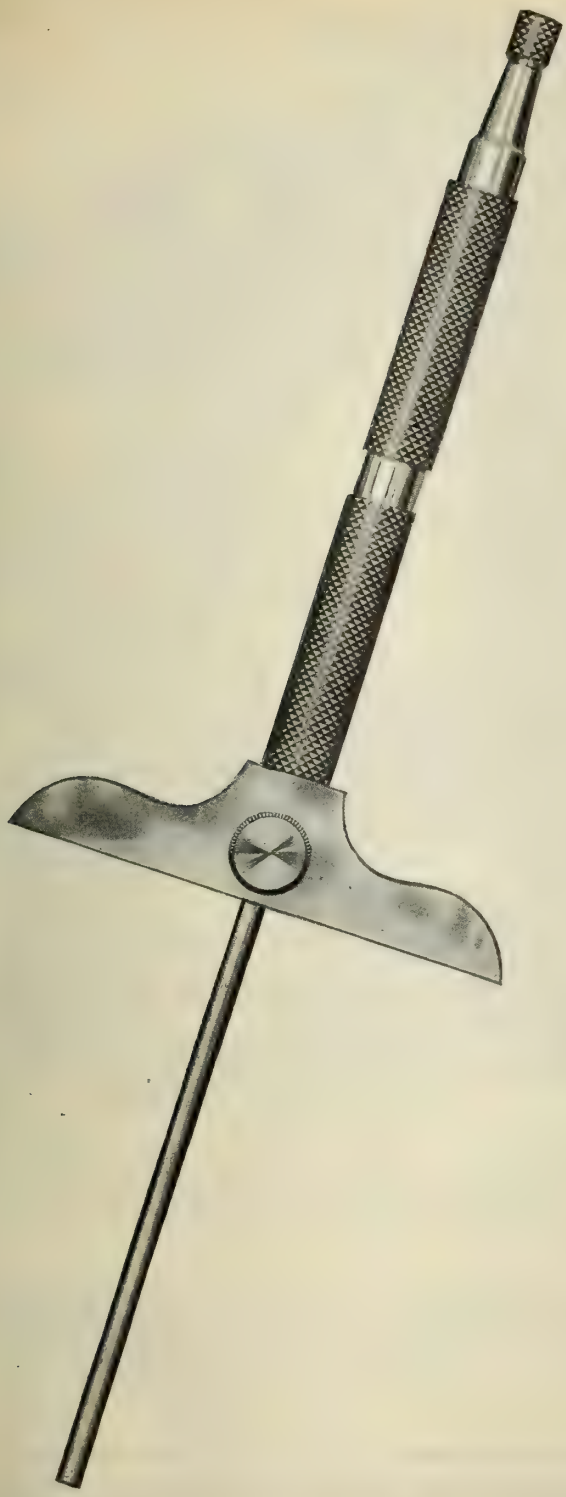
RAWHIDE CONDENSITE CELORON OR METAL



For quick measurements

The new Starrett Spring Depth Gage No. 48 is proving immensely popular with machinists and mechanics. Its convenience is obvious. A spring inside the barrel of the tool forces the rod downward until stopped by the bottom of the hole or recess to be measured. Then a quick turn of the clamp screw locks the rod in position and the gage is securely set with an instantaneous accurate measurement. Capacity of three inches—base is two and one-half inches long (a longer and better base than on the average gage). Base and contact end of measuring rod are hardened and ground. Starrett quality throughout.

Write for Catalog No. 22"3" and the Supplement describing the new Starrett Tools.

Two 3 phase Kaelin Electric Steam Generator Units for 6600 volts, designed and built by us for the Laurentide Co., Limited. Capacity of units shown, 7000 boiler horsepower, all controlled by a single operator on each shift.

The generator shown at the left is typical of sizes from 75 to 400 boiler horsepower for 3-phase power. Note its compactness and convenience.

"Can our idle power be made to conserve our coal pile?"

It's worth finding out and we have the answer.

A number of plants producing or purchasing power but not using it fully at week-ends or other periods are turning this surplus energy into heat by means of

The Kaelin Electric Steam Generator

(Patents applied for)

thus securing remarkable reductions in their bills for coal or other fuel.

The saving in labor is also quite important. Altogether, the generator often pays for itself within a short time.

We build these generators in sizes from 5 to 3,500 boiler horsepower, for pressures up to 200 lbs.; also in sizes from 5 to 75 boiler horsepower for low pressure steam heating.

When desired, any of these generators may be equipped with automatic pressure or surplus power control.

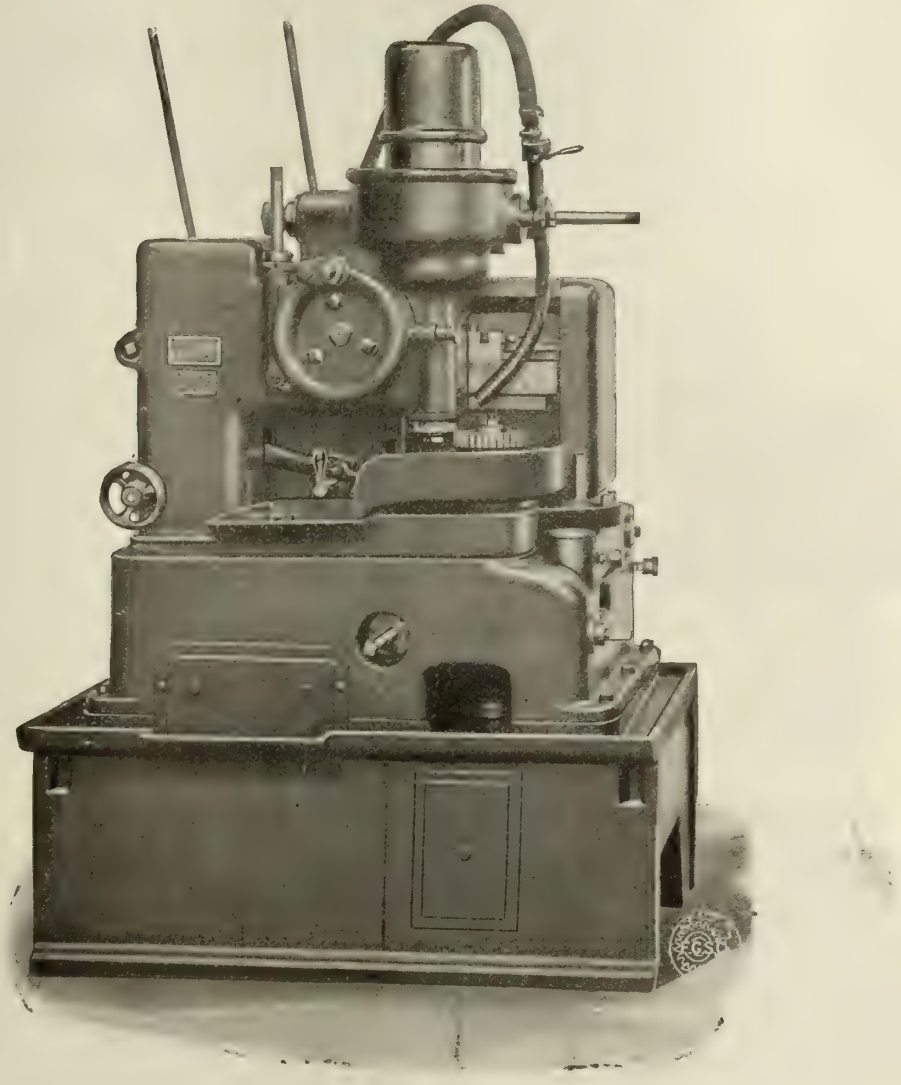
CUT GEAR COSTS
WITH THE
New Production Gear Shaper



The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.

It is designed to cut one gear at a time and at a speed which eclipses all other methods.

All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines

It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.

See illustrated article in all technical magazines.

Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

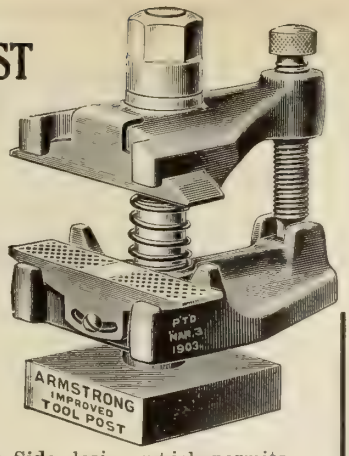
AN IMPROVED LATHE TOOL POST



This Armstrong Lathe Tool Post has many improvements on the ordinary tool post. Being stronger and stiffer it will not slip or chatter which means more accurate work. The rocker jaws adjust themselves on parallel lines, giving a great range of adjustment without loss of holding power. An important feature is the **Open Side** design which permits rapid and convenient change and adjustment of tools. It is, moreover, peculiarly adapted to working close to the chuck, there being no side projection. The Body Parts and Jaws are Drop Forged of Steel, hardened; other parts are Bar Steel.

A Typical Landis Performance

Greater Production and Economy were found by the Jackwill Mfg. Co. of New York, when they installed a battery of 5 Landis Threading Machines.

The one shown, a 2-in. Pipe and Nipple Threading Machine turns out with one operator, every eight hours, 900 2-in. nipples, threaded 1½in., 11½ threads to the inch.

This is a typical Landis performance, the honors of which are divided between the machine itself and the Landis Die, which like the machine, will give maximum service at minimum cost.

By comparison, a Landis Die has a life 20 times that of any other, with lathe tool cutting principles superior to that of the hobbed type die.

Be guided by the proven performance of more threads per dollar.

"Belting trouble ends where D.K. McLaren's Belting begins"

There's no doubt that economy of operation is the greatest factor of the ultimate profit in any shop. Operation costs, in their turn, depend largely upon efficient transmission. Therefore slippage and other belt troubles are direct charges to overhead.

D. K. McLAREN'S

Genuine British Oak-Tanned

LEATHER BELTING

is accepted in many of the largest shops practically as an insurance against belt trouble.

Made from only the back portions of selected hides, it is subjected to the genuine British Oak Tanning Process—a slow, expensive process that not only adds to the original toughness of the hide but imparts that wonderful flexibility and "stretchless quality" that means "trouble-free" service.

Only after every inch of belting has passed the severest tests is this Oak Leaf stamped upon it.

Experience has taught many users to look for this Oak Leaf. It's a guarantee of "service on the pulley."

Norton Alundum Elastic Cutting Off Wheels Are Indispensable For Tool Room Use

How often have you wished you had a grinding wheel for cutting off hardened or high speed steel, for salvaging drills, or for doing some special tool sharpening work?

We are manufacturing here Norton Alundum Cutting-off wheels up to 12″ in diameter and 1-16″, 3-32″ or 1-8″ in thickness, designed for just such operations.

We are equipped to supply you promptly in any quantities and in abrasive, grain and grade to give you maximum service.

If you have not seen for yourself the cutting speed of these wheels and demonstrated the advantages to your own satisfaction, order one for trial and test its value. If you will mention the kind of work you have, you will enable us to select the best wheel for you without any delay.

Any grinding problem you have, no matter what it is; we would like very much to help you solve it.

This piece is made on a Wire Feed Screw Machine equipped with a special chuck which allows the stock to run eccentrically when the screw portion is being turned and threaded. The stock is then centred by the special chuck and the ball is cut with a forming tool.

This piece is also made from the uncut bar. The entire portion below the plain flange is cut with a forming tool. The knurls are then rolled on and the portion above the flange is turned. The recess above the flange is cut with a rack tool.

BROWN & SHARPE WIRE FEED SCREW MACHINES

Adaptable Machines for All Types of Work

The easy method of opening and closing the chuck by a trip lever in front adapts these machines to work on bar stock previously cut in sections and to second operations on partly finished pieces in addition to the ordinary production from the uncut bar.

By using a special chuck or collet, irregular shapes, small forgings or castings may be machined with speed and accuracy.

Besides the variety of work they handle to advantage, the ability of these machines to solve successfully many production problems, should not be overlooked. The short run, which would not warrant setting up an automatic, can be economically produced on a Wire Feed Screw Machine. For the quantity job needed in a hurry, a Wire Feed Screw Machine can be easily tooled up and rapidly operated, producing work of a uniform size and quality.

Operative Construction of Levers and Treadles

Outlining Various Designs to Meet Specific Requirements—Providing for Adjustment—Locating for Convenience of Operation —Lever Operated Clamping Fixtures—Effect of Vibration

By FRANK H. MAYOT

HAND lever and foot treadle construction, design and location is a subject of vital importance to everyone engaged in machine manufacture and to all who use the same, for in any machine where a lever or treadle is not properly located time is lost in the operation of that particular machine and certainly if a lever in constant use is located "five feet from where you aint," about half the time some form of dissatisfied expression will be used against the maker of such a product.

Machinery of different types present their own problems of design and with this in mind a number of constructions are presented herewith which are typical of what are in use, covering an extensive field in a suggestive manner that they may help in the solving of that question "What to use?" While the entire range of hand lever and foot treadle design has not been covered a sufficient number are shown to make it apparent that there are ways and means to place these units where needed.

Plain Lever Design

Figure 1 shows a treadle and lever of familiar design and points to be observed in the construction of these apart from that of having sufficient strength of material and the proper leverage to perform the work at hand are few but important. In designing a foot treadle a feature often overlooked is the advisability of surating the flange A where the foot rests to prevent the foot from slipping off, also any outstanding projections against which the knee or shin of an operator will be struck are to be avoided, while of course a long boss where it rocks on a shaft is desirable to prevent excess side motion, as any play or looseness in the bearing will be multiplied considerably at the end of a long foot treadle. To counteract this it is sometimes desirable to have a yoke which straddles a long foot treadle near its outer end to prevent such side play. A hand lever should have the hand grip well rounded at the top as an operator is apt to place the palm of the hand over the top of the lever when operating the same. Various means are employed for attaching units which are to be operated by hand levers or foot treadles in place. A hole B is provided in the particular treadle shown in which a connecting rod is attached; the hand lever C pivots on a bearing at D while a yoke is attached by a stud at E in the make-up of this particular construction.

Varied sections of material are used in making both levers and foot treadles, this depending to some extent on the specific purpose for which used but more often on the temperament of the designer. If but one lever or treadle is to be made and this of cast iron the section of the lever would probably be made as shown at F, this being of rectangular cross section with the corners slightly rounded. The edges of this might be rounded as shown at X. The same lever would probably be made of the section shown at H if used in machine construction of standard design where a large number of castings were to be made from one pattern, as this oval type would be as suitable as a rectangular section and be neater in appearance and lighter in weight. The rib section shown at G is sometimes used although this requires more work to make the pattern and the castings obtained from such a pattern would require more cleaning. However, where very light weight is desired it is often used.

Toggle Action

A striking example of a lever operating a toggle action is shown in Fig. 2; here the lever A which pivots on a rocker shaft D pushes the link C to which it is connected through the medium of the rocker shaft D, a stud E connects link C to a pair of links F which are in turn attached by a stud G to a sliding block H. It will be evident that operating lever A causes shaft D to revolve as the lever is keyed thereto at J and K. This in turn causes link C to operate link F thus moving the sliding block H. A pull on the lever in the direction of the arrow X causing the block to be pushed in the direction of the arrow Y. In this particular construction of lever it will be noticed that the lower end of the lever is made to

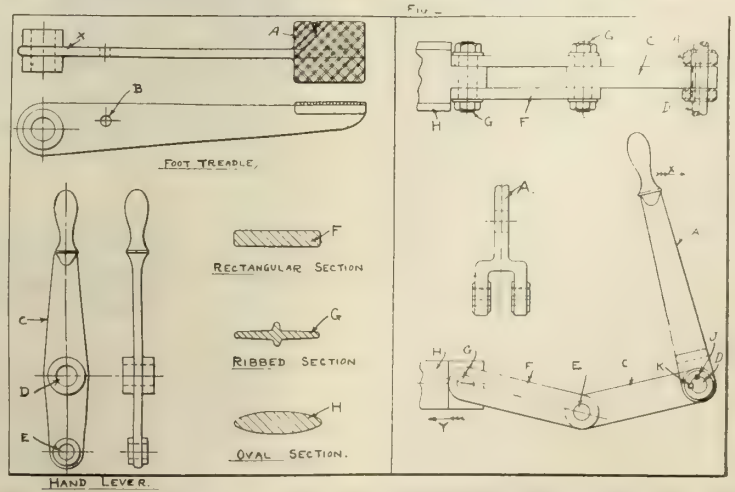

Fig. 1.—Left: plain foot and hand lever construction. Fig. 2: Hand lever and toggle construction for operating slide.

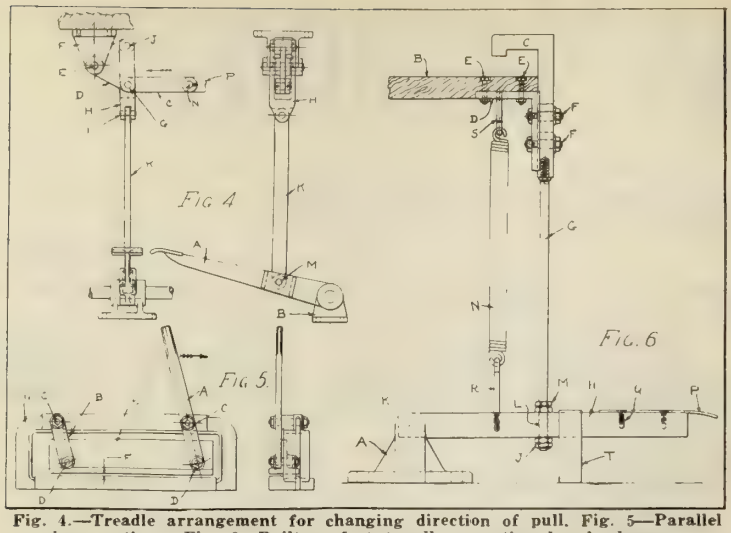

Fig. 4.—Treadle arrangement for changing direction of pull. Fig. 5—Parallel lever action. Fig. 6—Built-up foot treadle operating bench clamp.

straddle link C, reference to the sectional view clearly illustrating this feature.

A rather interesting development in the study of levers is brought out by a consideration of the features of construction shown in Fig. 3. In the center of this illustration a square paper trimming knife is shown; this is a hand operated machine in which an operator pulls on a long lever A which causes a knife B to descend and cut a stack of paper or other material. This is accomplished through the medium of another lever C, which is operated by a connecting rod D through the medium of a connecting link E. It is the action of E in conjunction with D and C which should be closely followed out in the following description.

Referring to the view at the upper left which shows the action of these three units, C pivots at F, and revolving shaft G causes link H, which is fastened to G, to pull on connecting rod D which is attached to C at J. This causes knife B to be pulled down through the medium of a connecting stud K, all of which arrangement it will be noted is direct lever action depending upon the lever ratios for the multiplication of power. At the upper right of this illustration is shown a construction used in an improved design of machine where lever C pivots at F and in the same manner as that at the left it operates knife B through the medium of stud K, pulled down by a connecting rod J. This connecting rod is for the same purpose as D at the left, except that connecting rod J is made adjustable, being threaded at both ends with right and left hand threads and made of hexagonal shaped steel bar stock. Attached to the shaft G is the same type of lever H but herein lies the basic difference, for in addition to H a connection L is used; this is shaped so it will clear the shaft G and is so set that lever H when pulled in the direction of the arrow will pass in an arc underneath shaft G, thus a greater travel of H will be necessary to pull down rod J, and in turn knife B, the same distance as in pulling down the same with a construction such as is shown at the left. Thus the power obtained from this design with mechanism of the same size will be greatly multiplied over that of the other construction. This action can be utilized to good advantage for the particular purpose shown, as the power required for making the cut is much greater near the bottom of the knife stroke than at the beginning of the stroke where the knife is being simply brought down to commence cutting.

Another feature which is of great importance to an operator should be observed in this connection; this is that lever A is adjustable radially on shaft G, it being tightened thereon by a nut M, co-acting surations radially made in the inner face of this lever engaging surations in a flange N, which is permanently keyed to the shaft, insuring that the lever will be securely held at the various radial positions where set to suit the particular class of work being operated on. A weight P attached to the opposite end of this shaft G counterbalances this entire mechanism so that the operator merely pulls over the lever to do the cutting and the entire mechanism returns through the medium of this weight. This example clearly illustrates the advantage of proper relative lever design to bring out the maximum utility of the mechanism at the most natural position for operation with the least amount of effort on the part of the operator.

A foot treadle construction whereby the direction of pull is changed to a right angle pull in an opposite plane from the lower action is shown by Fig. 4. This is sometimes called an end pull and its operation is such that by pushing down foot treadle A which is held to the floor by a bracket B, connecting link C is pulled in the direction of the arrow with a downward and endwise movement. This is accomplished by having a triangular shaped piece D pivotly connected at E in the bracket F, which is attached to the underside of the machine or to other suitable place where this action would be employed. The connecting link C is attached by a stud at G to D and yoke H is also attached by a stud at J to the upper end of this triangular piece D, while connecting this yoke H and the foot treadle A is a connecting bar K, it being attached in place by a pin L, at the upper end and a pin M at the lower end. Thus a downward pull on K causes D to pivot upon E as a center, thus moving C at right angle to K in a circular motion which may be changed to a straight motion by having link C connected at N to a sliding member, which would be indicated as P.

It will be observed from Fig. 4 that this entire arrangement of connections are universal in their action, sufficient pivot points being provided so that all tendency to cramp the levers is eliminated. As the downward movement of A operates K with a rocking movement,

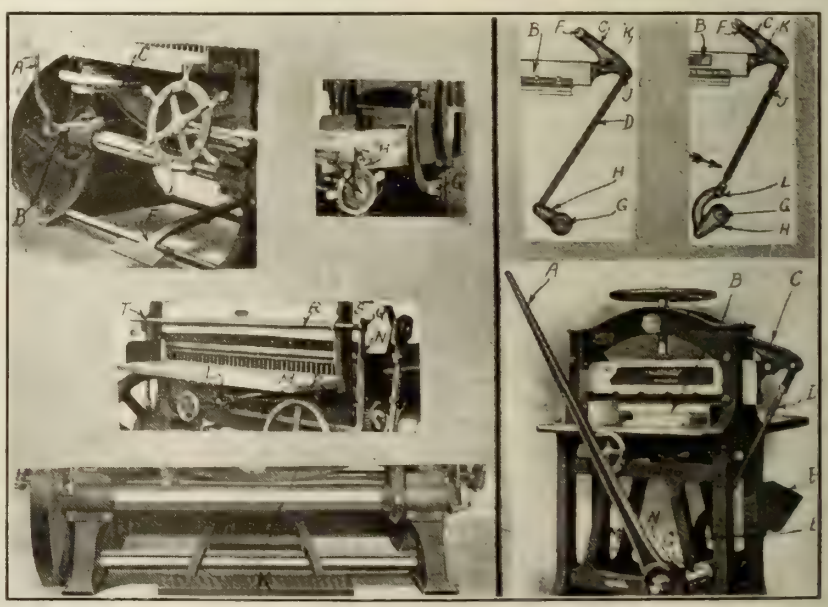

Fig. 7: A group of foot and hand lever constructions. Fig. 3: Right: two methods of proportioning lever action in a cutting machine.

which in turn operates H with a rocking movement, the lower end of K, where stud M enters the hole, being bell-mouthed to allow K to rock sideways slightly. This is a very powerful and desirable construction where a powerful action at right angles to the foot action is desired.

Parallel Action

Figure 5 shows a parallel lever action. To be effective this requires two links of equal centers, and in this construction the lever A in connection with the link B both having centers C and D of equal distance apart, operate a block E by swinging the same down parallel to the base and giving it a sideways movement. It will be evident that an operator in using this grips lever A and pulls it in the direction of the arrow which causes E to be carried downward thus causing material to be compressed between the two surfaces at F. Block E is mounted to A and B by studs at D while studs C hold the lever and link to the frame structure.

A complete example of a foot treadle operating bench clamp is shown in Fig. 6. One of the features of this construction is that, with the exception of the cast iron floor bracket A, everything is built up from steel so as to quickly construct the arrangement without waiting for patterns and castings. Casting A could also have been made from a block of steel except that it happened to be on hand. Referring to this clamping arrangement B indicates a bench while C is the clamp. This clamp is held to an angle bracket D which is held to the bench by two bolts E. C is held in D by two shouldered studs F with nuts thereon. A groove being cut in D to guide C, elongated slots being cut in C to allow it to travel up and down where the shouldered studs go through. A connecting rod G is attached to the lower end of C and this rod also passes through a steel bar H, two nuts J on the lower end of G enable H to push down G, thereby operating the bench clamp C. This bar H is connected at K while the hole L is made large so as to allow the bar G to be free to float slightly in H. Two check nuts M force rod G up when the bar H is pulled back by spring N, as the foot is removed from the foot treadle of which the bar H forms a part, plate P held thereto by screws Q, completing the foot treadle. The spring end is attached to H at the lower end by hook R while the hook G at the upper end holds it in place under the bench.

An additional feature of this construction is that a bracket T made of bar steel forged U shaped is attached to the floor, this forms a double purpose as it guides the bar or foot treadle H, preventing side movement or excessive play of the same, and also limits the up-motion of clamp C by treadle H coming in contact with its upper surface of this bracket. In use the operator merely pushes down on P and thus work is clamped between the bench and C, while removing his foot from the treadle allows the spring N to return the entire mechanism to its starting point.

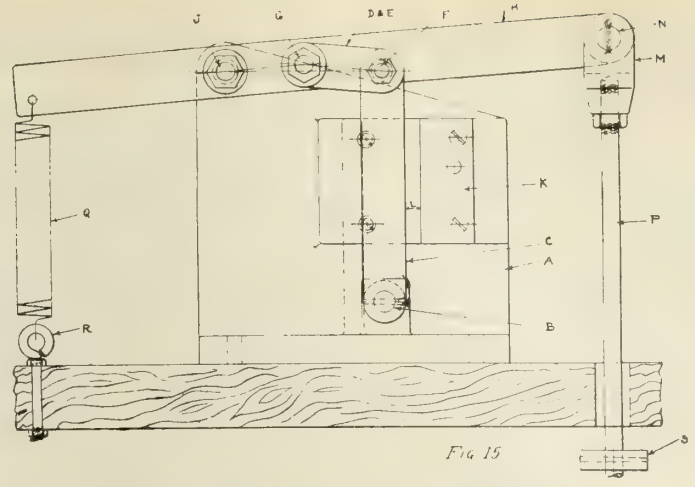

Fig. 15.—Toggle action lever and squeezing fixture.

Broad Foot Rest

An interesting group of lever constructions are shown by Fig. 1, these are intended to be suggestive of what are in use in machine design. The upper left hand corner shows a view in which a lever A is attached to a shaft B, this is held in place by a key and set-screw. Another lever is shown at C while the hand wheel D is also in effect, a lever being constructed with handles, making it of a pilot wheel construction. A foot treadle E is also shown in this connection making four features in all and it will be noticed that the end of this treadle is flanged out to provide a broad foot rest. In the upper right corner is shown a construction employing two levers, F being a plain rocking lever shaped so that the handle will set vertical on the machine and stand away from the frame while the bearing with shaft G is attached close to the machine frame. The other lever H is connected to a shaft J so that it operates in a radial manner and by means of a ratchet controls a radial feeding arrangement.

In the lower view is shown a foot treadle K. This is constructed so that it will reach about half the width of the entire machine, it is ribbed and is light weight, the width being desirable so that an operator can step on the foot treadle from most any position in front of the machine. It should also be noted in this connection that the upper portion of this corrugated treadle is made removable so that as the corrugations wear down another corrugated plate may be attached. The view in the center shows a rocking lever L and in addition a construction is shown which while it cannot be termed a hand lever

(Continued on page 53)

Heating and Ventilation in Relation to Health

System of Forced Ventilation Not Sufficient—Air Should be Thoroughly Cleansed—Natural Renovating of Out-of-Doors System—Impure Air Responsible for Many Diseases

IN connection with the crusade that is being carried on in many parts of the country by heating and ventilating engineers to educate the public to a proper appreciation of the necessity for adequate ventilation of their public and other buildings including their homes, a careful review of the subject will prove interesting reading to the engineer and layman alike.

"While it is admitted," states an authority on this subject, "by all thinking people that ventilation must promote health, it is not realized to what extent the converse of this statement is true; that is to what extent ill health is caused by insufficient or ineffective ventilation."

Macfie, in his recently published work, "Air and Health," says: "Air containing merely the CO_2 and moisture usually contained in vitiated air will not produce the effect of vitiated air, and vitiated air, therefore, must contain an additional constituent. This additional constituent, though undetected by chemists, is probably detected by the nose, for it is well known that air is oppressive and harmful not so much in proportion to the amount of CO_2 and moisture it contains as in proportion to its smelliness. The very fact that the nose is so sensitive to such odors would seem to suggest their harmfulness."

Outer air contains, of course, more or less dust which when admitted to a building tends to settle. Dr. Prudden observes that even ordinarily efficient systems of ventilation do not carry off any considerable proportion of the dust particles from closed still rooms . . . and when by a system of forced ventilation we cause large volumes of dust-laden air from out-of-doors to pass through them, we are actually, so far as micro-organisms are concerned, cleansing the air and sending it out much freer from germs than when it entered, these having slowly settled as the air makes its way from the entrance to the exit of the ventilating openings. When we consider the comportment of dust particles in closed rooms, we see at once that the great renovating and cleansing agencies which are so efficient out-of-doors are, except on special occasions, absent, namely, the winds and strong air currents and the more or less frequent and prolonged wettings . . . . A rainfall, to a certain extent, tends to free the air of its germs by washing them down. We should always remember that bacteria do not become detached from the surfaces or materials on which they grow or are lodged while these are in a moist condition. The most obvious means to prevent the accumulation of dust within enclosures is to remove it from the entering air.

While the harmful effect of foul air may not be immediate further than its effect on one's comfort or mental acuteness, it is generally conceded that frequent and protracted exposure to such air, as in the case of poorly ventilated school and factory buildings, results physiologically in a lowering of the vitality of the occupants, rendering them more susceptible to disease and considered economically, results in a lessened efficiency on the part of the occupants.

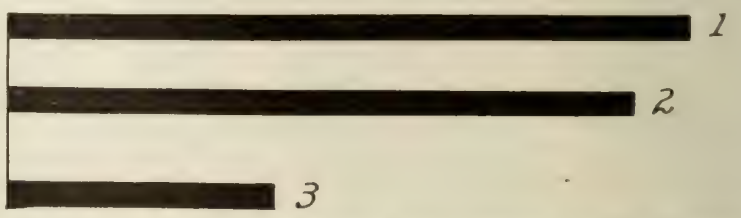
Tuberculosis and pneumonia are most prevalent among persons living or working in unventilated rooms. These diseases are caused by specific bacteria which, for the most part, gain access to the air passages by adhering to particles of dust which are inhaled. To bad air we attribute much of the anaemia, the pallor, the neurasthenia, the general ill-health of factory workers and most persons engaged in sedentary indoor occupations. Very moderate amounts of dust particles in sensitive persons cause a degree of irritation of the respiratory organs as either to deprive them of robust health or predispose them to the acquirement of various diseases which with unirritated lungs they would readily resist.

"As to the bacteria," says a prominent physician, "there are unfortunately a few species which, when they once find lodgment in one place or another in the organs of respiration, may grow and multiply, and successfully resisting all the protective agencies of the body, set up distinct, persistent and even fatal disease. These forms of bacteria which can or in these regions commonly do this, are insignificant in number in comparison with the harmless species with which dust is usually swarming. But few as they are they have an extreme significance. If it were not for these few species of disease-producing bacteria people could afford to be as indifferent as they are to dust and its dangers. . . "

It has been pointed out among the causes of atmospheric vitiation and discomfort that high temperature and humidity have much to do with the oppressiveness of the atmosphere in occupied spaces. As to desirable and practicable relative humidities in rooms occupied in winter by persons in health, taking into consideration the cost of maintaining a high relative humidity in cold weather and the trouble from condensation on windows, a temperature range from 40% to 50% according to the weather rather than a higher relative humidity.

Humidity in Manufacturing Plants

Pure air is fully as important in influencing production as warm fingers. Adequate ventilation, therefore, is as vital a factor in summer as in winter. Curiously enough, humidification has developed in the minds of most mill men as a purely mechanical proposition. Proper attention has not been given by factory men to the indirect effect of humidity which is upon the working capacity of the operative. Unbiased British officials and certain American engineers have demonstrated that, considered both immediately and ultimately, the direct or mechanical value of humidity works on parallel lines with the indirect or operative-working-capacity effect, and that the best results in dividends are secured



(1) and (2)—Percentage of factory force absent in two successive years before adopting scientific ventilation. (3)—Reduction during third year, after installing proper ventilation.

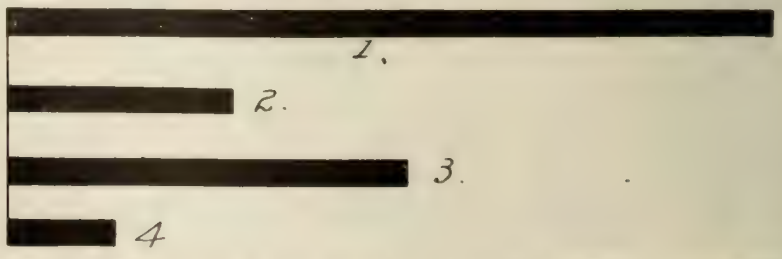


Chart showing reductions in deaths in large hospital due to improved ventilation. (1)—Percentage of deaths in surgical ward before and (2) after installing proper scientific ventilation. (3) Percentage of deaths in other wards before and (4) after installing proper ventilation.

by considering direct and indirect (mechanical and personal) effects together, in other words taking the resultant of the two working factors.

In certain buildings, where the results of changing from poor to good ventilation have been carefully observed, a marked improvement in the general health of the occupants has been manifest. The gain effected is not to be measured alone by the days' absence saved, but by the greater vitality and efficiency of the entire working force. Even though there be no method of ventilation provided, the mere abundance of space per occupant secures a certain air change owing to the fact that no partitions, floors or ceilings are perfectly tight, hence the greater the space per occupant the greater the surface of surrounding walls, etc., and the greater the accidental air leakage of spontaneous ventilation as some put it.

Prof. Winslow, of the Mass. Institute of Technology, in a paper on "The Cash Value of Factory Ventilation," mentions that: "Efficient production requires skilled and practical workers, in good physical condition, applying themselves, with energy and enthusiasm, to their tasks. Irregularity of attendance, and the physical sluggishness and nervous inattention which accompany lowered vitality, mean direct money loss to the employer of labor, as well as a burden on the community at large."

Perhaps nothing has focused the attention of the general public on the necessity of fresh air so much as the crusade now being waged against tuberculosis. Dr. Woods Hutchinson, in his book, "Preventable Diseases," brings out in a most vivid manner the wonderful changes wrought in the prevention and treatment of this disease. He advises us to learn to sit or sleep in a gentle current of air all the time we are indoors. If ventilation could be had for little or no cost above that for heating alone, there would not be the "hue and cry" against it on the part of those whose "pocket nerve" is touched. The fact, however, that in cold climates adequate ventilation costs money should not be allowed to stand in the way of its more general compulsory adoption. Those who are most in need of it are, as a rule, less able to demand it, hence the necessity of the strong protecting the weak through the enactment of legislation to secure to children in schools, to adults in public buildings and to workers in factories and shops, an adequate volume of pure fresh air. It is not pleasant to consider that in crowded, unventilated rooms the air must be breathed and rebreathed, nor is it pleasant to consider the other causes of atmospheric vitiation within enclosures as pointed out.

Tempering is shown to be that process wherein the hardness of a piece of steel is let down or tempered to remove the brittleness and make it tough.

LOCALIZING THE HEAT IN HARDENING PRACTICE

THE immersion method is the best for many classes of work. The reasons are the elimination of scale, the good control of heat and the rapidity of the operation, which thus localizes the heat and keeps it from spreading to adjacent parts. The commonest form of material for the heating bath is lead. It is best to secure lead fairly free of tin to prevent particles of the lead from adhering to the work. Pig lead is furnished for hardening purposes, which is very pure. The slight extra cost will be warranted by a minimum of lead sticking to the work. Even pure lead will stick to the work unless the hardener keeps the surface of the lead free of dross and well covered with charcoal.

It is always best to skim the lead surface soon after it melts in the morning and then cover with lump charcoal of ½ inch to 1½ inch size. As the charcoal burns away it should be renewed. The skimming operation should likewise be conducted after the noon hour. The burning of the charcoal forms a gas which excludes oxygen from the surface of the lead, thus preventing dross or lead oxide from forming. If the lead pot is unused for a period of say ½ hour, a metal cover should be placed over the pot. This will cause the charcoal to last longer.

Neutral salt baths are used to a great extent for local heating. The operation of heating by immersion is the same as for lead. The surface of the bath, however, need not be protected. The heat conductivity of salt being less than lead, it will require a greater time of immersion to heat the work.

Numerous kinds of metallic salts can be utilized for heating steel. Their melting points are so diversified that combinations may be made which can be kept molten at any temperature from 400 deg. F. to the melting point of the steels, and their volatilization will be slight. The writer recommends the following mixtures of barium chloride and potassium chloride to give the least amount of loss of salt by volatilization at temperature indicated.

Temp. Deg. F.	Bar. Chlor. Per Cent.	Pot. Chlor. Per Cent.
1300—1400	12	88
1400—1500	25	75
1500—1600	37	63
1600—1700	50	50
1700—1800	70	30
1800—1900	88	12
1900—2400	100	0

Other neutral salts, used both for tempering and hardening, heating by immersion, are equal parts of potassium nitrate and sodium nitrate for temperature ranges from 400 deg. F. to 1075 deg. F. Sodium chloride (common salt) or a mixture of sodium chloride and potassium chloride for temperatures from 1200 deg. F. to 1650 deg. F. Calcium fluoride or magnesium fluoride for temperature ranges from 2700 deg. F. to 2900 deg. F.

Carburizing or nitridizing salts are used for local heating. They not only leave the work clean but also add a skin hardness of a few thousandths to the surface. These salts are commercially available. The most used is the commercial 76 per cent. sodium cyanide, 27 per cent. sodium cyanide next, and then 98 per cent. sodium cyanide. There are many cyanide salts under various trade names. These materials are in the main satisfactory. As they are generally advertised to give off no poisonous fumes, they seldom contain sufficient amount of cyanide to warrant long life. This defect is sometimes an advantage as certain combinations of neutral salts with cyanide salts give, at certain temperatures, a minimum of volatilization. This prevents undue loss of the cyanide gas.

The cyanide process of P. W. Shimer and G. B. Shimer is being used to a greater extent. Roughly this process consists of adding a strongly cyanided salt to a neutral salt; the neutral salt merely acting as a vehicle. An important feature of salt baths for local heating is the film of molten salt which adheres to the work on its removal from the bath and which prevents oxidation of the work in transference to the quench. The quenching medium usually dissolves or scatters the salt immediately. Torches and specially designed furnaces are sometimes used to heat certain sections, but are not generally used to economical advantage.

POINTS FOR HACK SAW USERS

A contemporary gives the following advice on the use of hack saws: Don't strain the blades more than is required to keep them taut, as an over-tightened blade will not endure the addition of the working stress. At the same time, a slack blade is equally liable to be broken. The pressure put on a new, sharp saw should be much lighter than what is advisable when the teeth have begun to wear, as new teeth, if crowded too hard, are liable to dig in and break. The pressure should also be proportioned to the thickness of the saw. The safe rule is to maintain that pressure which keeps the blade cutting, and such a speed that the blade does not become overhot. A lubricated saw can be run much faster than a dry saw, but the cooling liquid must be copious and applied directly at the point of cutting. It should be noted that insufficient pressure, by allowing the teeth to skid over the work without cutting, causes the teeth to glaze and dull quickly. Also, that teeth once overheated become too soft to cut any more.

Truing of a wheel is the name given to the operation which has for its purpose the removal of material from the cutting surface of the wheel, so that the resulting surface is geometrically true. It is not necessarily a sharpening operation, but aims solely to produce a true cutting surface.

Self-Contained Coal Dryer, Pulveriser and Blower

Cheap Grade of Coal Used to Advantage—Any Desired Rate of Delivery—Preliminary Drying Process Unnecessary—Complete Combustion—Small Proportion of Paraffin Used

CONSERVATION of fuels is perhaps a matter that will more vitally concern the next rather than the present generation, but it is one that ought to occupy a prominent place in our scientific and industrial research work to-day. Cheapness of production, however, is an important present-day problem and one to which we must bend our untiring energies if we are to maintain our prestige and position in the world's commerce. Not the least factor in the cost of production is the item of fuel costs. With individual plants consuming over a thousand tons of coal per week and others using hundreds of tons of oil, the cost of fuel must bulk very largely in the annual balance sheet.

Of the various fuels available, pulverised coal would seem to offer many advantages from the point of view of cheapness. In the United States pulverised coal as a fuel has received much consideration and it has been widely adopted in many large power house plants. At the River Rouge boiler plant of the Ford Motor Co. the four supposed largest boilers in the world are fired by pulverised coal and blast furnace gas. This method of firing was only adopted after an exhaustive survey of all possible types and it would seem to indicate that there are potentialities in powdered coal that will well repay the careful consideration of fuel users.

In the cement industry it has been standard practice for many (about 60) years for firing rotary kilns. Whatever may be the impression regarding this fuel for other applications, such as boiler houses and furnaces, there can be no two opinions on its superiority for cement work.

In the utilization of powdered coal as a fuel there have been in the past both advantages and disadvantages. Among the latter were the costliness of the pulverising plant, the inadvisability of storing the powdered product for use, and difficulty in dealing with the ash. If these can be eliminated or at any rate considerably depreciated, there would seem to be a wonderful future for powdered coal. The advantages it claims are cheapness of fuel, extraction of most of the heating value, low labor costs, and the fact that low grade coal can give good results.

In the past a powdered fuel plant has not only been costly to install but equally costly to maintain and run, entailing, as it does, a coal dryer, with its auxiliary furnace, a tube mill or other pulverizer, elevators, conveyors, separators, bins and bunkers for storage, fans, etc. With the new invention named the Atritor all the disadvantages mentioned above are said to be eliminated. This machine dries, granulates, pulverises to any degree of fineness and delivers the fuel into the combustion chamber all in one continuous process as and when wanted, at any desired rate of delivery without any auxiliary plant whatever other than a feeding arrangement for the coal.

The first Atritor was put into commission about 12 months ago. During the intervening period this machine and two others have been subjected to very rigorous tests in the course of much experimental work. The machine as designed is known as the No. 10 size and it is guaranteed to give, with an actual power consumption of 30 h. p. an output of 1,800 lbs. of coal per hour pulverised from ¾-in. lumps to a fineness such that 95 per cent. will pass through a 100 x 100 mesh screen. A larger machine is also in contemplation.

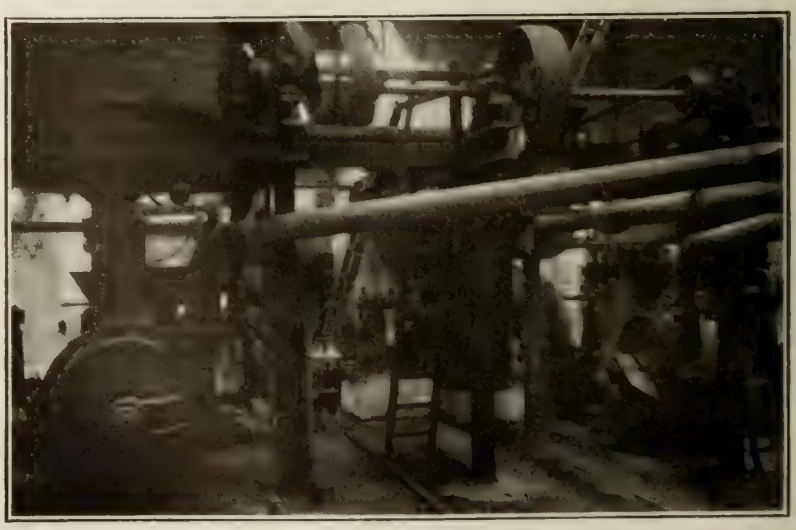
A typical Atritor installation as applied to two 140 ft. x 8 ft. rotary cement kilns is shown in the illustrations herewith and consists of two Atritors driven by 40 h. p. electric motors, each with a 10-ton raw coal hopper for feeding and an elevator for keeping the hoppers full, with a screw container from the elevator to one hopper. It is recommended that 40 h. p. motors be installed for driving this size of machine, though it will give full output when grinding coal not exceeding ¾ in. in any direction at 30 h. p.

An installation similar to that shown is capable of burning over 800 tons of cement per week. It is, however, advisable to have a third Atritor as a standby in case of breakdown through any cause. It is a simple matter to arrange the delivery pipes with flap valves so that any of the machines can deliver its product at the piont desired. The cost of pulverising coal by the Atritor system at Stockton is about 62c per ton, while by the old installation it was about $1.25 per ton.

Another decided advantage of the Atritor system of burning the fuel immediately is the fact that a lower grade of coal can be used with consequent decreases in cost. With the old type of plant a large part of the volatile combustible matter in the coal is lost during the drying operations and storage. The approximate difference between the lowest grade coal it was possible to utilize by the old system and the coal which can be burned quite satisfactorily by the Atritor system is about $2 per ton delivered at the works. The total costs for fuel burnt in the kiln, that is delivered at the works, handled and pulverised and propelled into the kiln are, therefore, $2.65 per ton by the old installation against $2.40 per ton by the Atritor.

The advantages of the Atritor system for pulverising coal may be summed up as follows:—

1. It is a small, self-contained unit for drying, pulverising and propelling the fuel direct into the combustion chamber ready for burning, in one continuous process.
2. It will deliver any quantity at any rate desired as and when wanted up to its capacity of 1,800 lb. per hour.
3. It is continuous in action and dis-



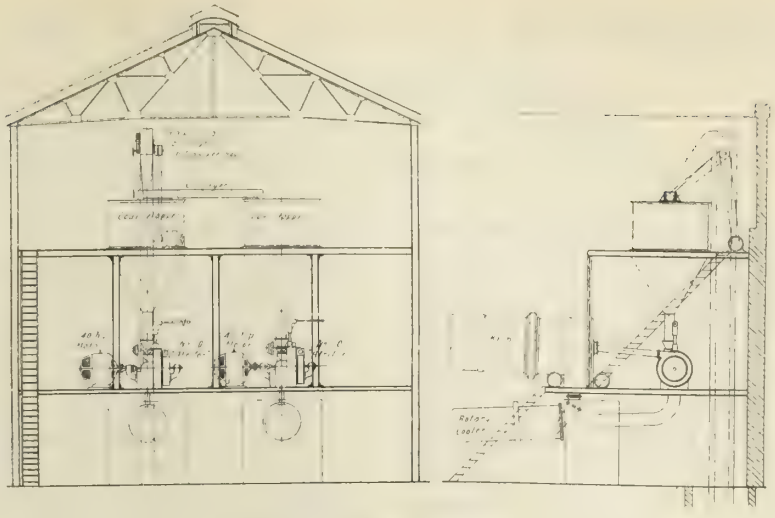
General installation of Atritor unit.

Photos and data through courtesy of Alfred Herbert, Ltd., who are the licensees and manufacturers.

penses with the necessity for storage bins.

4. It can be started and stopped at will.
5. The drying and pulverising go on together and the product is burned immediately without opportunity to absorb moisture after pulverisation. This is important as powdered coal is extremely hygroscopic.
6. The whole of the combustible contents of the coal pass into the furnace and are burned. There is no opportunity for the volatiles to be lost. This is a very important point as considerable waste of volatiles takes place during drying and storage under the old system.
7. It entirely supersedes the elaborate, expensive and dusty plant hitherto employed for the purpose.
8. There is no necessity for any subsidiary plant other than a feeding device for the raw coal.
9. The cost of the installation is low. The power consumed is low. The cost of maintenance is extremely low. The labor cost is low.
10. It is entirely dustless in operation.
11. The moisture contents of the coal make no difference to the working of the machine or to the resultant product.
12. The hot air supply for drying can be drawn from any convenient source of waste heat.
13. No smoke or soot is formed and no combustible matter left in the ash.
14. Pulverisation may be carried to any degree of fineness desired.
15. A high temperature can be obtained very quickly.
16. By the addition of a minute amount of paraffin (a patented process) (.07 per cent. by weight of coal pulverised) the time for heating up is reduced by 75 per cent. A rotary kiln is ready for use 40 minutes after lighting up.
17. The addition of paraffin also enables coal which is unburnable when ground by other means to be successfully burned by this system.
18. There is no heat wasted nor waste of fuel when damping down.
19. There are no screens used and therefore no clogging of material.
20. An efficient metal separator is incorporated in the inlet end of the machine. This dispenses with the use of a magnetic separator.

Interior of Atritor showing arrangement of pulverizing pins.



Layout of Atritor installation.

The addition of paraffin during pulverisation has produced such almost extraordinary effects that the process has been patented. The requisite amount for firing up is .07 per cent. by weight of fuel burned or about 1½ pints per hour to 1,800 lbs. of coal. The paraffin can be shut off when full heat is attained, or it can be kept on when pulverising very inferior coal in order to assist in maintaining the temperature.

The mechanical features of the Atritor consist generally of: (a) A hopper with variable screw feed driven by cone pulleys and worm gearing and level operated slide, for regulating the flow of raw coal. (b) A coal chute and metal separator in which any material of heavier specific gravity than coal is thrown out and thus prevented from injuring the machine. (c) Hot and cold air supply ducts. (d) A casing with fixed pegs of extremely hard metal in concentric rings on both sides. (e) A rotor disc with similar pegs on each side and rejector pegs on one side. (f) A suction and blower fan cased in a scroll. In the scroll are auxiliary air ports.

The coal feeds through the slide and screw and falls towards the centre of the machine where it is met by a strong current of cold air which is being drawn through an adjustable opening in the front of the machine. The air draught is adjusted to the amount of coal feed so that all the coal is pulled into the machine but anything heavier than coal rejected, falling down to the air inlet, thus dispensing entirely with the necessity for a magnetic separator. The pull of the fan and centrifugal force throw the coal through the intermeshing rings of pegs in the first disintegrating chamber, called the first effect.

The coal particles are then drawn by suction towards the centre again through the chamber known as the second effect. It will be noticed that the rings of pegs go completely across the first effect, so that the coal has no loophole to escape their smashing action. In the second effect, the rotating rings of pegs only go across half the chamber, leaving half the volume free except for stationary pegs. The innermost ring on rotor is composed, however, of pegs which go completely across the chamber and enter a recess in the casing on the other side. This ring acts as a rejector for coal particles that may be still too large for use. In addition a set of eddy currents are set up towards the centre on the side of the casing and towards the periphery up the side of the rotor disc. The circulation thus set up in the second effect completes the pulverisation until the particles of coal are so impalpable that they are drawn by the fan and propelled into the furnace.

For full capacity of 1,800 lbs. per hour with only 5 per cent. residue on 100 x 100 screen the slide under the hopper should be full open and the screw feed on the fastest rate. Hot air should be drawn in at a temperature of round about 450 deg. to 600 deg. C. At this temperature coal of a high moisture content will be completely dried in its passage through the machine. The auxiliary air ports in the casing on the delivery side should be shut. If for any purpose the required output is to be less than the above, the slide should be closed first and the cold air inlet regulated so that no coal is rejected by the metal separator. For a still smaller output the screw should feed at a slower rate and the slide worked in conjunction. The cold air will have to be adjusted until coal is not thrown out by the separator. This may necessitate the opening of the auxiliary air ports to give sufficient air for combustion.

A safe rule when using a hack saw is to maintain an even pressure and to keep blade cutting.

Adjustable Boring Tools an Aid to Production

Quantity Output Requires Effective and Accurate Tools—Economy to Use Roughing and Finishing Tools—Hard Scale Soon Destroys the Cutting Edge—Close Adjustment

IN THE construction of machinery, especially of the finer variety, the boring of holes of all lengths and diameters proves to be one of the greatest factors in the problem of production. Where manufacturing is carried on in a big way and the question is largely one of quantity as well as quality, it is of essential importance that adequate and reliable facilities be provided for the proper performance of the work. When the quantity of output is small and the character of the work is of comparatively wide range the solution of providing efficient tools and equipment is rather difficult, owing to the possible excessive cost of tools.

However, where the requirements demand the continuous operation of a certain tool for long periods, the problem becomes less complicated, as it is more economical to provide special equipment and tools for the particular operation. In the boring of holes, large and small, the service of a boring bar is almost imperative. In many shops the practice of using forged boring tools on much of the lighter work still exists and on the larger parts the home-made boring bar with the inserted bit continues to serve the purpose, but the modern production plant to-day has adopted more up-to-date methods in the machining of holes and interior surfaces.

For the most efficient work it is necessary that the equipment used meet the specific requirements of the work in hand. Where the volume is sufficient it is invariably advisable to have a boring bar for each size and length of hole; this practice may be advantageously modified in the case of moderate production to tools having a wider range of application.

For the general run of lathe work a short threaded end is usually adopted for placing on the end of a bar that is held in the tool post, and which may be adjusted to the desired length of hole. These end pieces may be adapted to boring through or blind holes. When possible it is an advantage to provide a steady bush in the lathe spindle, in which a pilot on the front end of the bar enters before the tools come in contact with the work; this gives added rigidity to the bar and increases the accuracy of the boring operations.

When bars and cutters are in constant service allowance must be made for wear and regrinding of the tool bits. In many bars manufactured for this class of work provision is made in the bar for accurate setting of the tools to the desired size. This is usually accomplished by means of an adjustable wedge fitting between the two inner ends of the tool bits. Some bars are equipped with a graduated screw by which the setting of the tools can be accurately and quickly made.

The accompanying illustration shows a boring tool set-up on a turret head operating on a variety of work in a large manufacturing plant. The boring operations on this particular piece are held to close limits on two separate diameters. Separate tools are used for roughing and finishing each diameter, thus insuring maximum efficiency and greatest production. These boring tools are expanded to compensate for wear by means of a micrometer adjustment, the graduations permitting of setting to thousandths of an inch, making possible the use of the fastest speeds within reason. Both cutters in these bars are expanded uniformly on the wedge principle and are rigidly locked. The pilots are hardened and ground and provided with oil grooves, the lubrication assisting the free movement of pilot in the bushing and adding to the rigidity of the bar under the action of the cut.

One of the principal factors in the maintenance of cutting tools is the presenting of a clean surface to the finishing or sizing cutters. It is always advisable to have separate cutters for roughing and finishing. The wear on the former will often be excessive, especially where scale on casting or forging is met with. The more frequent grinding on roughing tools necessitates greater replacement but this is more than compensated by the increased production when finishing tools are not brought in contact with hard scale. The wear on the sizing tools will be very slight and very often a light touch with a hand stone will maintain a keen edge for a considerable time.

COPPER AND BRASS

High brass, low brass and copper may be quenched after annealing if desirable. Muntz metal and leaded brass however, should be air cooled. In the case of the muntz metal rapid cooling markedly alters the miscrostructure and the temper of the metal in an undesirable way. In the case of leaded brass quenching results in "sweating" of the lead.

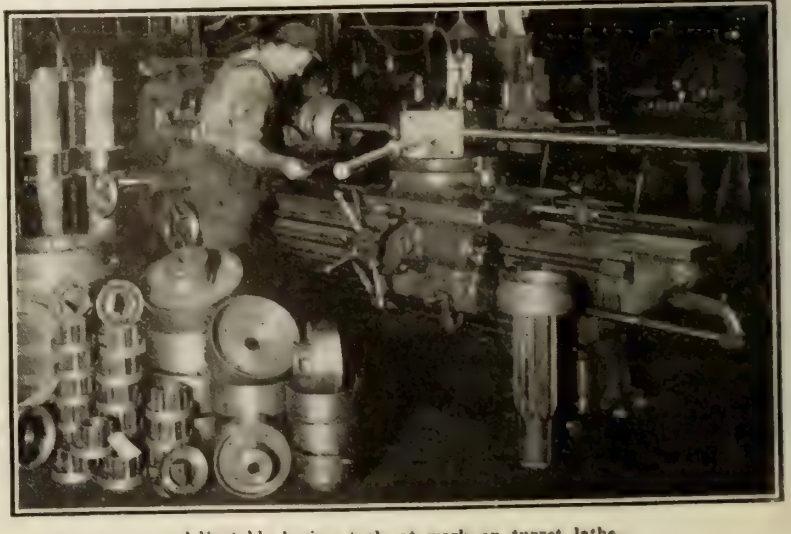
Copper and brass containing 90 per cent. or more of copper show only a slight difference in actual hardness after annealing at various temperatures above 900 deg. F. High brass on the other hand, shows a large difference in hardness under similar treatments. For this reason high brass is adapted to such uses as require fine graduations of temper.

Corrosion does not necessarily favor the development of season-cracks in stressed brass. Very severe corrosion and pitting caused by the prolonged action of various acids and other corrosive agencies had no cracking effect on stressed brass.

It has long been recognized that the presence of a hard and strong constituent in an alloy may strengthen it by opposing the "flow," or slip, of the weaker constituent.

TRANSMISSION POINTERS

Short drives and vertical belt drives should be avoided, or used only in cases of emergency, as they necessitate very taut belts. The moment a vertical belt stretches under strain, it loses its grip on the machine pulley beneath. The short horizontal drive requires very tightly set beltings with side pull on the shaft hangers out of all proportion to the normal strain for which the bearings are adapted.



Adjustable boring tools at work on turret lathe.

Questions and Answers

Canadian Machinery and Manufacturing News would have its readers feel that its resources for gathering special information, such as they may require, are freely at their service. Their questions will receive immediate consideration. On the other hand, should they feel that they are in a position to add to the information given in these columns upon any subject, their co-operation will be greatly appreciated. Desired information is first sent by mail to enquirers. Names will be supplied upon request.

Manufacturer.—We are placing a floor surfacer on the market and should like to know whether inspection of the apparatus by the Hydro-Electric Commission is essential. I understand the fee for inspection is $75, with a fee of $10 for re-inspection the second year. This strikes me as a rather high figure. What is the object of this inspection? Is it compulsory?

Rules and regulations embodied in the Ontario Power Commission Act of 1916-1918 and authorized by Order-in-Council, provide that design and construction of certain electrical machinery, apparatus, appliances, devices, material or equipment must be approved by the Hydro-Electric Power Commission before they may be used or disposed of in the province of Ontario. The purpose of these regulations is much similar to that applying to steam boiler inspection. The object is to provide a standard for the design and construction of electrical materials, devices and fittings, of all kinds, the proper observance of which would eliminate, in the use of such material, devices and fittings, as far as is practicable and reasonable, risk of injury to persons and property and also of fire. In short, the regulations are a safeguard against defective design, construction, workmanship, installation and operation on apparatus employed by unskilled users, largely in office, shop or home service. Manufacturers and vendors of such apparatus are also required to see that it is not used in connection with sockets of too low rating, and all electrical installations shall be so located or protected that damage will not be likely to result to persons, property, or equipment.

Manufacturers or owners of patent rights must make application to the Hydro-Electric Power Commission for test and approval of the apparatus they desire to market within the province, and in order to be assured that the manufacturer will construct his product in exact duplicate of the samples approved the Commission makes periodic tests and inspections by way of re-examination and label service. The label consists of a suitable marking, indicating that the apparatus has been inspected.

All of the large electrical goods companies, such as Canadian General and Westinghouse are, of course, subject to these regulations; there are no exceptions. They do not apply to the same extent to large power-house installations having skilled engineers in charge. The fees range from $45 to $300 according to the apparatus and the amount of work involved in the inspection. Where the costs do not aggregate the amount of preliminary fee, the balance is returned to the submittor. The fees cover only one examination and one set of tests on one device, system, method or material. A request for further examination or set of tests is considered to be a new application and may require payment of a second preliminary fee.

Would suggest that inventors of electrical apparatus, or those proposing to market same, secure a copy of rules and specifications for test and approval of electrical material, devices and fittings, issued by Hydro-Electric Power Commission of Ontario.—Ed. Canadian Machinery.

Blast Furnace Operator.—What were the amounts paid by the Federal Government to Ontario furnaces on pig iron made from domestic ore from 1896 to 1905?

The total amount paid was $1,335,379.76, divided as follows:—Algoma Steel Company, $190.754.05; Antikokan Iron Co., $47.703.19; Canada Iron Corporation, $204.897.96; Deseronto Iron Co., $10 029.60; Hamilton Blast Furnace Co., $98,126 66; Hamilton Steel and Iron Co., $783,227.22; Standard Chemical Co., $641.03. For pig iron production made from foreign ores, the amount paid in bounty was $1 830.161 58. In addition, the Ontario Government paid $125,000 in bounties to miners of domestic ore between 1896 and 1905. During the 26 years from 1896 to 1921, out of a total of 17 512 562 tons of ore smelted Ontario supplied 15.5%, and foreign ores 84.5%. There were, evidently, not sufficient supplies of native ores available. Prof. G. C MacKenzie of the Metallurgical Institute, Montreal, observed recently that if all of the 17,512 562 tons of domestic and foreign ores smelted in 26 years had been of domestic origin, the bounties paid at the rate of 54 cents per ton—on a total of 2,705,720 tons of domestic ores smelted in 26 years—might have amounted to $9,400,000, which compares with the sum of $43,977,000 estimated to have been expended in foreign labor and supplies on imported ores. "In other words," he says, "the old bounty acts were good business, but the moneys expended were not sufficient to offset the amount sent out of the country for the purchase of foreign labor and supplies."—Ed. Canadian Machinery.

Foundryman.—In your market reports I notice that under the heading of scrap metals you quote only dealers' average buying prices. Why do you not quote dealers' selling prices as well?

Dealers' buying prices are what are chiefly required in the main activities of the metal market. Machine shops and manufacturers generally, have large quantities of scrap to dispose of. They desire to know at what prices they may dispose of it. On the other hand, iron foundries are small buyers, in comparison with blast furnaces. In fact, many foundries buy their scrap iron locally. Another fact is the grading of the metal. There are numerous grades, representing differences of opinion, as to what may be required for certain purposes. The dealer must be informed on this matter before he can quote. The question of individual credits is another feature of the business, and also the location of the purchaser in relation to source of supply. A large dealer explains the matter briefly by stating that "every case in which scrap is being bought from us by the small local foundry, has to be considered on its merits; that is why we can quote no price that will apply to the requirements of the market as a whole."—Ed. Canadian Machinery.

Laporte.—Kindly inform me where possible to procure a one-half horsepower engine.

Enquirer has not stated whether steam or gas engine is required or for what purpose. The Elgin Gas Motor Co., Elgin, Ill., make a half horsepower gas engine such as used for washing machines, churns, etc. It is handled in Canada by the A. R. Williams Machinery Co. A half-horse rotary steam engine is made by John Whitfield Co., 33 Sherbourne St., Toronto.

Dressing is the process of cleaning or resurfacing the cutting surface of a wheel. It breaks up the surface so that the wheel may cut properly. Dressing is a sharpening operation and does not necessarily true a wheel.

Manufacture and Treatment of High-Speed Steel

Charge Should be Heavy and Clean—Tungsten Turnings to be Added Gradually—Furnaces Must be Carefully Examined After Each Heat—Forging the Ingots—Making Large Cutters

By H. K. OGILVIE

THE following notes deal chiefly with the manufacture of high-speed steel in the basic-lined electric furnace. Although the crucible is still largely employed as a melting medium the method is of little technical interest, being entirely a melting operation as no refining is possible, and a small amount of sulphur is generally absorbed by the metal. Although this element is not quite so dangerous as in ordinary carbon steel it is nevertheless advisable to keep it under about 0.06 per cent.

The labour and fuel costs are extremely high, but the plant and overhead charges are much lower than in the case of the electric process. The cost per ton of sound billets, however, certainly is in favour of the small electric furnace, even when the latter is only working nine or ten hours per day. The steel properly made by the two methods seems to be equally good, and this is important, as the material cost is only a small proportion of the total cost of an average form tool.

Most of the crucible steel is cast into small ingots weighing up to a few cwts. each, and so long as the alloys have been completely melted there should be little segregation and few surface defects. When forged into bars for turning tools, small cutters, and drills, the structure should be fairly homogeneous and uniform throughout. It sometimes happens, however, that small particles of tungsten compound are not completely melted, particularly when tungsten powder is used. These form extremely hard spots having a Brinell hardness generally over 600 when tested with 1-millimetre ball and a load of 30 kilogrammes, and they persist throughout the subsequent operations and may completely destroy a fine-toothed cutter working on the otherwise soft material. It is thus desirable to introduce the tungsten by means of ferro-tungsten or by the use of a tungsten-chromium alloy.

Melting the Charge

The electric furnace is commonly used for melting this class of steel, and the charge may consist entirely of high-speed steel scrap together with a small amount of turnings. The latter should be heavy and clean and are placed under the electrodes and on top of the scrap until a bath is formed. Where a large amount of tungsten steel turnings have to be used up it is preferable to add them gradually to the charge after it has been melted, but it is very much more economical to use only good scrap, that is, heavy clean scrap, with a tungsten content, and to reject light and rusty turnings.

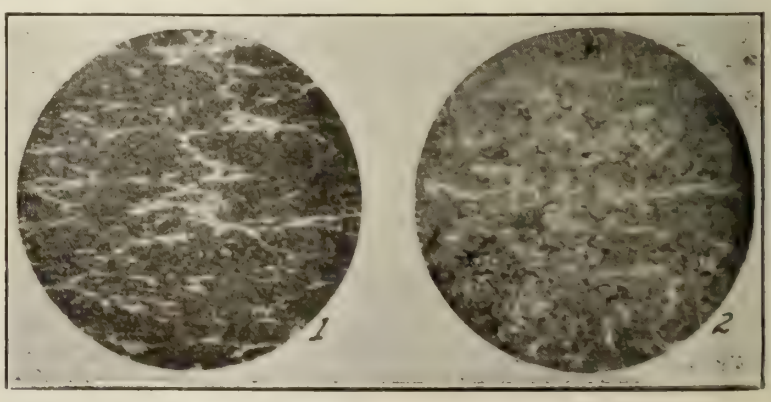
To attempt to make good high-speed steel from turnings alone, or where the greater part of the charge consists of turnings, is not, in this country, commercially possible. One cannot determine with accuracy the percentage of elements present, and this may necessitate the addition of large amounts of expensive alloys. If the turnings are clean and oily the carbon in the metal when melted will probably be too high: if they are rusty it will be too low with considerable loss of chromium in the slag. The latter will be saturated with oxides and must be removed from the furnace, as time cannot be spent in reducing these into the steel. Even when using heavy clean turnings which can very seldom be obtained in bulk, the loss will be at least 10 per cent. With average turnings bought from a scrap agent the loss may be 20 per cent. or more. Added to this is the difficulty of melting the turnings without breaking the circuit or damaging the bottom, together with the increased repairs necessary to the banks of the furnace. On account of the high current and electrode costs every suggestion which tends to shorten the length of each heat should be encouraged, consistent with making good steel but in any case the time should not exceed 4½ hours for a 3 or 4 ton furnace.

When good scrap is charged the melting slag is comparatively clean and need not be removed, and the sample for analysis can be drawn as soon as the bath has been stirred up. During the next hour, while waiting for the content of carbon, tungsten, chromium, and vanadium, a heavy lime slag should be carried without getting the metal too hot. Probably a small amount of lump ferro-silicon may require to be thrown into the bath to deoxidise the steel completely, and slag should be kept as white as possible, taking care that it is heavy enough to prevent the coal or ground electrode which is sprinkled on it from passing through into the metal. During this time most of the sulphur is removed from the steel.

Reducing the Oxides

The electrode coolers should fit closely enough to prevent the space between them and the electrodes acting as a chimney and drawing a stream of cold air through the furnace having due regard at the same time to the slight variation in diameter of the electrodes themselves. With badly fitting electrode coolers, apart from the heat lost and the increased repairs necessary to the roof, the length of time required to reduce the oxides in the slag is prolonged whilst the consumption of electrode per heat is surprisingly increased. The doors should be heavy and a good fit. Double arches may be used with the best silica brick inside the furnace and ordinary firebrick on the outside, the latter withstanding rapid charge of temperature much better. A bricklayer accustomed to this class of work can keep down the costs of repairs enormously, and will seldom interfere with the normal working of the furnace.

As in every other class of melting, attention must be paid to the furnace bottom and banks after each heat, particularly at the top of the banks where siliceous material from roof and walls tends to gather. In the case of furnaces having a bottom electrode where the bottom is often considerably weakened by iron spikes or metal to increase its conductivity, it is very important to completely remove any metal from pockets left after tapping the furnace. These should be carefully filled up with magnesite or dolomite mixed with a little



basic slag and allowed to partially fuse. Where a furnace of the Heroult type is in use probably the best method of making the bottom is that employed for the basic open-hearth furnace, using oil burners if no other means of reaching the necessary temperature are available. Layers of good quality burnt dolomite mixed with a little basic slag are fitted on until half the thickness is reached.

After saturating the bottom with slag and "setting back," the operation is continued, using layers of magnesite together with sufficient slag to render it just viscous at the maximum temperature obtainable until within a few inches of the necessary thickness. The top layers are completed with dolomite and slag and the furnace is finally held at a white heat for some hours by introducing coke between the electrodes.

Obtaining Analysis

By the time the metal has been melted the percentage of carbon, tungsten, and chromium should only be slightly reduced but most of the vanadium will have been removed. The necessary amount of crushed ferro-tungsten and ferro-chromium is added as soon as the analysis is obtained, and the temperature of the steel is gradually increased. When the bath is in good condition enough ferro-manganese is thrown in to give about 0.2 per cent. manganese, and five minutes later the ferro-vanadium may be added in a bag and well rabbled under the slag. The furnace should be tapped within the next ten minutes if the samples are quiet and the temperature sufficiently high, and no additions of aluminum or any deoxidising compounds should be made to the ladle or moulds. Occasionally at this stage when getting the metal hot enough to tap, the steel, in some of the smaller furnaces especially suddenly becomes wild, and if cast will rise over the tops of the moulds even when considerable quantities of carbon, silicon, manganese, and vanadium are present. It is useless to attempt to deoxidise the steel with additions of ferro-silicon, etc., and the only method which has given successful results in the hands of the author is to cool the steel without any addition until after thorough rabbling samples taken at regular intervals show the metal be sound.

It may be necessary in some cases to allow cooling to proceed until the steel commences to solidify round the banks. As this gas trouble has been quite widely known for a number of years, the author is rather surprised that so little mention of it has appeared in any of the home or foreign technical publications. Why high carbon steel containing up to 1 per cent. of silicon and melted with every possible precaution should, without any visible indication, suddenly become so wild as to flow out of the test ingot requires some explanation, when the slag is apparently in good condition and practically free from oxide of iron. It is difficult to believe that the trouble is due to oxide of iron, which can scarcely exist in such large quantities in the presence of elements having a greater affinity than iron has for oxygen. Also a sample ingot, badly honeycombed, after forging and rolling, showed apparently thorough welding of the gas holes, and gave impact and bend tests equal to sound steel of similar composition. At the same time there is undoubtedly a reaction between the gases and the silicon and manganese prese with the steel is sufficiently cooled with consequent slight reduction of these elements, but during the time the metal is hot and wild there is no greater oxidation of silicon manganese, or vanadium than normally takes place with sound steel under approximately the same conditions. Also the milder the steel to be made the more liable is the trouble to occur, taking into account the slightly higher casting temperature of the low carbon steel. This may or may not be due to the fact that no carburising material is added when the melting slag is removed.

While the temperature seems to be extremely important the method and rate of generating heat appears to be more so. No such trouble is met with in a furnace such as the Rennerfelt, where heating is done almost entirely by radiation, or in basic Siemens practice, where equal temperatures are attained so far as can be judged by the fluidity of the steel. The metal in the electric furnace is always hotter when the first slag requires removal than it is when ready to tap the furnace, and when a clean slag is put on and fused a small amount of ferro-silicon is sufficient to render the steel quite free from any tendency to rise in the mould. Yet as the refining proceeds and the slag becomes practically free from effective oxides, the danger of gas trouble appears to increase. In this way it is similar to overpoled electrolytic copper which, while theoretically free from oxygen, swells and evolves gases on solidifying. Although this gas trouble does not often happen with high-speed steel, attention is drawn to the fact that it is by no means unknown in arc furnaces.

It is important to remember that this class of steel oxidises in the sample spoon more quickly than carbon steel, and allowance should be made for this when judging the temperature of the metal. No instrument gives very consistent results in practice when attempting to measure the temperature of molten steel, but it is very seldom that the usual pouring of film tests when carried out under same conditions each time fail to give extremely good results. Where there is some doubt it is better to get the steel into the ladle too hot than too cold, especially if there is any device attached to the latter to regulate the speed of casting.

The ingots for each melt should not vary greatly in size, and octagon moulds are to be preferred. Castings should be done from the top of the mould, having the metal in the ladle hot enough to permit the slag to rise to the surface, and as small a nozzle should be used as will pour the whole heat at such a rate that lapping of the ingots is just avoided and no crust permitted to form on the surface of the steel as it rises in the mould. This allows the ingot to solidify in the most natural manner, preventing the formation of large tungstide ne wo and keeping the pipe down to a minimum.

Result of Several Tests Made on Welded Cylinders

Method of Making Seamless Pipe—Process of Welding Girth Seams—Practice Followed in Testing the Welds—Results of Observations—Determining the Factor of Safety

By PROF. E. A. FESSENDEN and S. J. BRADFORD

FROM samples cut out of this cylinder for physical tests the actual mean thickness of the weld itself was carefully measured, and for welds made in ¼-in. plate the average thickness was found to be 0.350 in. Hence the actual stress withstood by the acetylene-welded seam during the test without any sign of failure was 24,500 lbs. per sq. in. This amounts to 8,590 lb. per linear inch of acetylene-welded seam. The stress which caused final failure of the forge-welded seam was one-half of this or 4,295 lb. per linear inch of seam.

Four samples were cut from one of the circular flange-steel blanks such as used for making the dished heads. The results obtained when tested for tensile strength are presented in Table 1.

Ultimate Strength

The ultimate strength of the plate tested was thus somewhat below that specified for flange steel as set forth in the Boiler Code of The American Society of Mechanical Engineers, where the requirement is given as 55,000 to 65,000 lb. per sq. in. The elastic limit, or yield point, is above the requirement which states that at the yield point the stress shall have a minimum value of one-half the ultimate tensile strength, i.e., 27,500 to 32,500 lb. per sq. in. The fractures were typical flange-steel fractures showing a very fine grain. The amount of elongation and the reduction in area were not determined.

Three samples containing sections of the acetylene-welded longitudinal seam were cut out of the cylinder and subjected to tension tests. Professor Patterson's report upon these specimens gave the results presented in Table 2.

The average ultimate strength was slightly above the value of 28,500 lb. per sq. in. specified by the Boiler Code of The American Society of Mechanical Engineers, for properly made forge welds (p. 45, Par. 186, edition of 1918). The average ultimate strength per linear inch of acetylene-welded seam was 10,097 lb. The fractures occurred in every case through the body of the weld itself, practically at the center line of the seam. In every case the fracture started with a crack which grew larger as the tension was increased. The final fracture did not occur suddenly and with a strong pronounced snap, as would be the case with a good flange steel, but was slow and gradual, as might be expected from a loosely knit, coarse, granulated material, and was very similar to that obtained when a piece of putty is pulled in two. The elongation was not measured, but if any occurred it was very slight indeed. There was no apparent reduction of area. The fractured heads indicate approximately the boundaries of sections later cut out for microscopic and metallurgical examination. The section containing the leak in the forge weld which caused final failure was cut into small pieces for examination and designated as specimens

TABLE 1 TENSILE STRENGTH TEST OF CYLINDER NO. 1 SPECIMENS

Sample	Dimensions in.	Area sq. in.	Load, lb. Yield point	Load, lb. Ultimate	Tensile strength, lb. per sq. in. Yield point	Tensile strength, lb. per sq. in. Ultimate
A	0.243×2.00	0.486	17,000	24,500	35,000	50,400

	Average			29,083

Extract of a paper presented at a recent meeting of the American Society of Mechanical Engineers. The first part appeared in the Oct. 19th issue.

Fig. 9—Final shape of cylinder No. 3 head, showing failure of forge weld.

Fig. 8—Head of cylinder No. 2, showing scale cracks indicating distortion.

PO, PI, PE and PZ. These samples were cut in the order given reading from left to right in Fig. 6, PE being the small sample containing the crack which caused final failure.

The construction of cylinder No. 2 is shown in Fig. 7. The shell was made of seamless-steel pipe approximately 0.34 in. in thickness. The heads were of dished form, with a straight cylindrical flange of the same external diameter as the shell and about 1¾ in. long. The heads were welded to the shell by the acetylene torch with the convex face outward. The cylinder was set up for testing like cylinder No. 1 and marked off into sections. Outside diameters (in inches) were measured only in the horizontal plane, before and during the test, as follows:

Observations of Test

Between sections	1-2	2-3	3-4	4-5	5-6
Before test ...	12.65	12.73	12.78	12.78	12.73
At 2,550 lb. per sq. in.	13.08	13.05	13.05	13.05	13.05

The following observations were made during the test at the pressures indicated:

600 lb. per sq. in. Faint cracking sounds heard at end of section.

1,200 lb. per. sq. in. Scale cracks were observed in the forge scale on each head at the sharp bend where the flange is formed on the head. These scale cracks are shown very clearly in Fig. 8, and indicate that sufficient deformation of the convex head to crack the scale had occurred.

2,000 lb. per sq. in. A very slight leak through the acetylene-welded circumferential seam joining the cylinder head to the end of section 1. This leakage was so slight, more in the nature of barely perceptible seepage, that during the entire test not more than three or four drops of water escaped.

2,550 lb. per sq. in. A small leak occurred where a ½-in. extra heavy pipe coupling was acetylene welded to the shell in section 5 of the cylinder.

2,600 lb. per sq. in. The leak observed at 2,550 lb. per sq. in. where the coupling acetylene welded to the shell in section 5 became so large as to constitute complete failure.

The progressive approach toward the truly hemispherical head was quite apparent.

The factor of safety, computed on the same basis as for cylinder No. 1, may be taken as one of the following figures: (a) If failure is considered as occurring when the first indication of deformation was observed (the cracking sounds heard near the head of section 6), the factor of safety is 3.24. (b) If the vessel is considered to have failed at the first apparent leakage, the factor of safety is 10.81. (c) On the basis of the maximum internal pressure reached, the factor of safety is 14.06.

Assuming the effective thickness of the weld to be the same as that of the shell material, i.e., 0.34 in., the stress in the circumferential seam at a pressure of 2,000 lb. per sq. in., when the first very slight leakage was observed, was 17,700 lb. per sq. in. on the basis of the original mean diameter of the shell. This amounts to 6,020 lb. per linear inch. On the same basis and the maximum pressure reached during the test, the stress on the seam was 23,000 lb. per sq. in. or 7,830 lb. per linear inch of seam.

Two test pieces containing circumferential-seam samples were cut out for tension tests. Careful measurements of the actual mean thickness of the seam gave an average value of 0.442 in. Using this figure instead of the nominal thickness of 0.34 in., the stresses withstood by the seam during the test were as follows: At the first slight seepage, 13,620 lb. per sq. in. of seam; For the maximum pressure, 17,690 lb. per sq. in. of seam. A number of samples were cut from this cylinder for tension tests. They were located as follows: Sample H was cut from the head of section 1. This sample may be located by reference to Fig. 8. It contained the letters GC shown at the top of the head. The very small seepage leak was also in this sample. Sample I was similar to sample H and was cut out of the head at the end of section 6. Sample J was a circumferential section cut out of the shell. The location was about 5 in. to the right of the coupling that caused final failure. Sample K was a longitudinal sample cut from the shell at a point about 6 in. away from the coupling that caused final failure and on the back side of the cylinder.

Professor Patterson's results for the tension tests of these samples are given in Table 3. For the shell material the elastic limit and the ultimate strength were each above the value specified for boiler-plate steel in the Boiler Code of The American Society of Mechanical Engineers. The elongation and reduction in area were not measured but were considerably less in amount than were obtained for the flange steel used for the heads in the tests described in connection with cylinder No. 1. The fractures were fine-grained.

The average ultimate strength of the acetylene-welded seams was slightly below that specified by the Boiler Code for good forge-welded joints. On the basis of the average ultimate strength of the acetylene-welded seam, it would require a load of 12,010 lb. per linear inch of seam to detach the head from the shell. The fractures of the acetylene-welded joints exhibited in general the same characteristics as were described for the acetylene-welded joints of cylinder No. 1, except that in sample H the welding material pulled away from the head, opening up the spot where the slight leakage occurred. At this point the color was somewhat darker than for the remainder of the fracture. All the indications thus point to poor adhesion at the junction of the head and the welding material, probably due to oxidation.

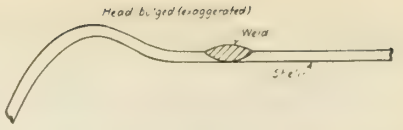

Fig. 10—Distortion of head at the end of section 1 of cyl. No. 4.

The shell was made of the same kind of seamless pipe as that used in the shell of cylinder No. 2, but about 6 ft. long. The heads were similar to those used in cylinder No. 1 and were forge welded to the shell in the same manner. The ends of the shell were crimped over to reinforce the forge weld, and like the other two cylinders, the shell was marked off into sections. The outside diameters (in inches) of the shell measured in the horizontal plane before and during the test were:

Between sections	1-2	2-3	3-4	4-5	5-6
Before test ..	12.64	12.76	12.81	12.81	12.75
At 550 lb. per sq. in. ..	12.66	12.76	12.83	12.81	12.75
At 1,300 lb. per sq. in. ..	12.70	12.76	12.81	12.80	12.75

The following observations were made during the test at the pressures indicated:

200 lb. per sq. in. The concave head in the end of section 1 began to show where the head had been somewhat flattened (presumably) during the process of forge welding to the shell.

550 lb. per. sq. in. The concave head in the end of section 1 completely reversed in curvature.

1,000 lb. per sq. in. The concave head in the end of section 6 became convex. The distortion of the head in the end of section 1 had increased markedly.

1,300 lb. per sq. in. The head at section 1 was stretching rapidly and slight leaks appeared through the forge-welded joint at both heads.

1,380 lb. per sq. in. Complete failure resulted from excessive leakage through the forge weld joining the head to the shell at end of section 1. The leakage was so great that it was not possible to increase the pressure further with the pump available.

(To be continued.)

Practical Ideas From Practical Men

DRILLING JIG FOR MACHINE LOCK NUTS

By Robert Mawson

When machining various parts by such operations as boring, reaming and counterboring it is often necessary to machine the hole to a certain pre-determined depth. Under these conditions the tool used for the operation is provided with a collar or similar medium which comes against the head of the guide bushing or similar surface so that all the holes machined with the tool in the various pieces will be similar as regards the depth of hole. The usual design for the shank of the boring tool is to make a threaded portion on which is screwed a nut or in some cases two nuts that may be adjusted to obtain the desired setting.

In Fig. 1 is shown the type of lock nut employed when only one nut is used which is considered the better method as the shank can be made with a shorter length of thread and as there is only one nut to make, the tool is somewhat cheaper. The chief advantage is the fact that the tool can be adjusted much quicker than the two-nut type as it is only necessary to slacken a set-screw and turn the nut on the thread of the shank to the new position.

In our designing department we design a large number of tools such as here noted to be used in the shop and in order to produce the lock nuts cheaply and interchangeably, though this is not of very vital importance except for tools which we sell with the jigs and fixtures made for outside concerns. We made the jig illustrated in Fig. 2. This tool is made with a cast iron body counterbored on one side 1⅜ in. diameter and ½ in. deep. Feet are provided at the top and bottom which are machined square with the center line of the casting and bored hole. These feet are made of sufficient height so that when the jig rests on the machine table the guide bushings are clear of the surface. The rear of the jig body is also machined so that the washer under the binding knob A will come against a finished surface.

Through the center of the jig is machined a ⅞ in slot B so that the clamp C will set in without interference. Bushings are provided in the tool to drill the two 3/16 in. holes and also slip bushings to drill the hole for the "L" tapped hole and also the ¼ in. clearance hole for the screw. The position of these holes may be seen by referring to the detail of the nut and comparing this with the assembled jig.

To use the jig the clamp C is first removed from the tool and the nut to be drilled slid on the plug F which is a good sliding fit inside the thread of the piece. The clamp is then slid into position being located with a shoulder on the pin G which it will be observed is provided with a shoulder on the outer end so that the clamp can be held securely in place. The knob A is then tightened and this action draws back the pin and the shoulder already noted coming in contact with the clamp pressure then exerted on the nut holds it securely in the jig.

Referring again to the nut it will be noticed that a binding slot has been machined at the upper end and it is necessary that the binding screw holes be drilled in a certain relative position to this slot. This is obtained with the screw H which is turned down at the inner end to ⅛ in. to fit this slot and the nut is therefore placed so that this screw will set into the slot of the nut to be drilled. The 3/16 in. hole is then drilled in the piece and the binding screw hole drilled for the screw and the ¼ in. hole machined, changing the slip bushings for the operations and the hole also tapped with "L" 16 threads per inch with the guide bushing removed.

The jig is then reversed and a 3/16 in. hole drilled opposite to the first hole machined with the jig resting in the new position on the machine table. The advantage of this jig is that the piece is easily and positively located by means of the machined plug which fits the inside diameter of the threaded nut, and the part is also quickly fastened into position with the clamp and knob operated screw so that no wrenches are necessary for its manipulation. It is therefore all that a drilling jig should be and has proven a time saver in service and should furnish ideas for machining other elements that can be followed by tool designers in other plants.

A DRILLING KINK

By G. Blake

During the writer's visit to an engineering establishment, he noted a man operating a drilling machine, drilling ¾ in. dia. holes in a cast iron frame about 6½ in. thick. The man had difficulty in getting rid of the drilling (i.e.) the small chips of cast iron. He was using a short length of ⅜ in. bore brass tube and endeavoring to blow the chips out of the hole, putting one end of the tube in his mouth and locating the other end of the tube in the hole and blowing as hard as possible. In addition to not getting the chips out of the hole he was causing a small cloud of very fine dust to float about which is not a desirable thing from a health point of view. When drilling small, deep holes it is

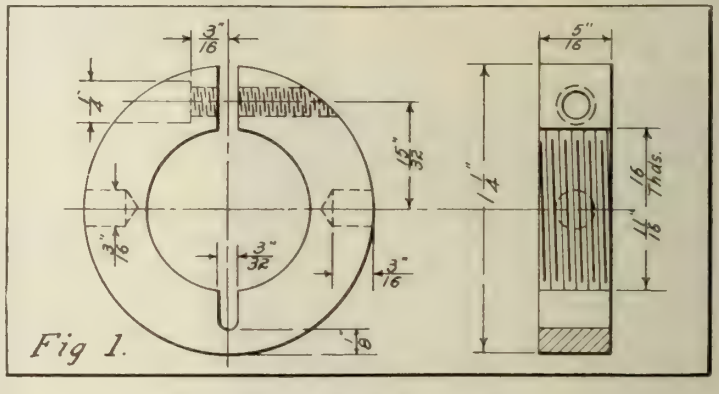

Fig. 1.—Type of lock nut for which jig was made.

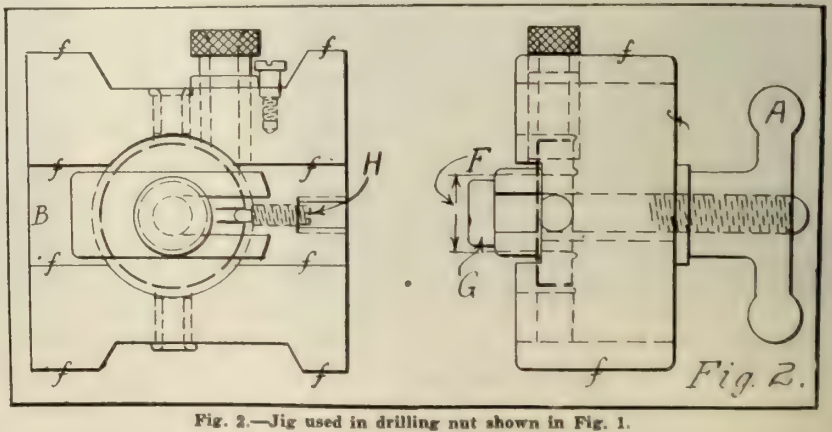

Fig. 2.—Jig used in drilling nut shown in Fig. 1.

best to provide oneself with a piece of silver steel, say from 3/16 in. to 5/16 in. dia. and about 12 in. long or longer, if the holes to be drilled are over 9 in. in depth, and have the end of the steel rod magnetized, this if inserted in the hole will get over the trouble in a few moments as the chips will cling to the magnetized rod. This small item should be included in every driller's kit.

LIFE OF EMERY WHEELS

By G. Blake

Generally when the emery wheel of the floor grinder is worn down to the flanges, it is scrapped as being of no further use. In the works where the writer is engaged, when the emery wheel has been worn down to the flanges, Fig. 1, it is taken off and the standard flanges removed and another pair of flanges smaller in diameter mounted as shown in Fig. 2; by this means the wheel is used as far as will permit with safety. In these days of rigid economy, a considerable saving in emery wheel cost will be effected if the above method is used. It is essential that the emery wheel be quite free on the spindle; if it is tight this increases the tendency of the wheel bursting. If possible when using the worn wheel the speed should be increased so as to maintain the standard peripheral speed of approx. 5,500 ft. per minute; if this is not done, the wheel will wear much faster as it gets smaller in diameter. After the wheel has been used as indicated in the above manner, it still has its usefulness, transfer it to your foundry to be broken in small pieces for rubbing down castings after being removed from the mould. It should be observed that the diameter of the flanges in all cases must be 1/3rd the diameter of the wheel.

PARTING TOOL FOR RING SEGMENTS

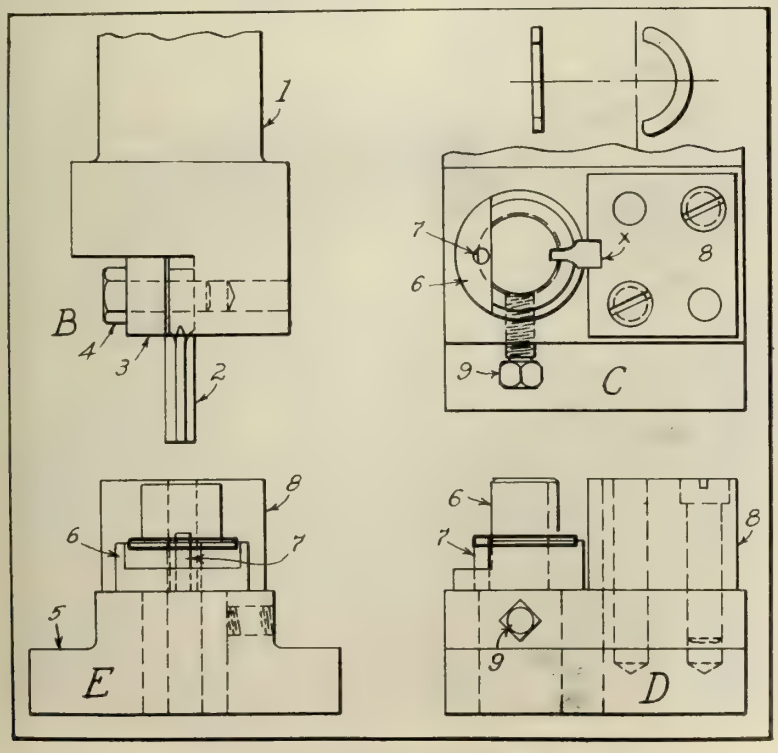
By F. H.

An interesting construction used for making segments from round rings which have been cut from tubing is shown by the accompanying illustration, where a completed part is shown in the upper right hand corner. This is a die construction in which the method of locating the work and backing up the cutting off punch is rather unusual.

Referring to the illustration this shows five views of which A and B are views of the punch holder and punch used for making the cut while C, D and E are views of the die. Referring to the punch holder, this is made of round machine steel it being indicated as 1 while 2 is the punch for cutting off, where it will be noted that the cutting off punch rounds the ends of the segments. This punch is held in position by a strap 3 and two screws 4, the punch holder being grooved to receive the punch which is made of rectangular-shaped tool steel.

In the die 5 is a steel block in which is attached a round piece 6 made from bar tool steel which acts as a cutting die. In this is located a pin 7 which is used for locating the work after the first cut is made. In addition a block 8 attached to 5 by screws and dowels is used, this has a groove cut in it at X, its purpose being to back up punch 2 which travels up and down in this groove thereby keeping the punch and die in alignment.

The ring from which the segments are to be cut (two in number) is placed over the upper end of 6, locating pin 7 being removed at this time. The punch press is then operated in the usual manner and the ring is split. After completing a batch of these rings in this manner the pin 7 is put back in place, the segment rings are again put over the end of 6 with the slot previously cut straddling the locating pin 7 after which the press is again operated which causes the punch to make the cut, and the resulting product is the segment shown in the upper right hand corner of the illustration, with both ends mounted. A square head screw 9 is used to hold the cutting die 6 in position and as the punch travels in the groove in 6 and is backed up by the groove in 8, correct alignment of the punch and die is assured at all times.



Parting tool for ring segments.

WHERE DID I PUT IT?

By D. A. H.

How many times do shop men ask that question? Hundreds of small shops have no tool room and no exclusive storage space; a foreman or other executive in such a shop has his hands full anyway and when he has to remember where some little tool that was used for Jones' job three years ago was put, he is really up against it.

One such executive got tired of wasting his time hunting in the lower shed or going through the drawers in the old desk or rummaging in the loft next the patterns or searching the shelves back of the boiler room. He could not work the management for anything better but these things had to be stored somewhere and someone had to hunt them up when they were wanted at a later date — as they always are, most unexpectedly. So he made out a list, kept in a note book under different headings such as "special tools," "sample pieces," "drawings," "fixtures for contract jobs," "discarded jigs, may be used elsewhere," etc., etc., and the book he titled "Where Did I Put It?"

Then when anything not active was put away, its location was recorded in the book. Days and days of expensive, exasperating hunting were saved by this practice. Efficiency men will say that such a method is starting at the wrong end, and so it is, but we on the firing line know what working under conditions of limited capital is and this homely method really passes the acid test of such conditions. Scores of harassed executives could follow this procedure with beneficial results.

CATALOG

The Bristol Co., of Waterbury, Conn., has just issued a new and revised catalog on their varied line of pyrometers. In addition to listing the instruments the book contains a number of specimen charts taken from actual installations. There are also several pages devoted to plans illustrating the correct method of installing the recording apparatus. The application of the fire ends is clearly described and demonstrated by a number of photos and line drawings, showing their adaptation under different conditions.

New Things in Shop Equipment

AUTOMATIC CENTERING MACHINE

Designed for use in the field of large production, the automatic centering machine has two heads which center work at both ends in one operation, and in addition has an automatic drill feed mechanism operated in conjunction with a magazine. Clamping of the work is also done mechanically so that after the set up it is only necessary to keep the magazine supplied with work and take away the finished parts. The work is removed from the magazine by transfer slides, placed in the vise, clamped, centered and then released into the work box independent of the services of an operator.

The feed to the drills is automatic, being operated by the same cam O which operates the transfer slides. This cam is driven by a small motor (shown in the rear view) and a set of change gears provides the means of adjusting the drilling time to suit the nature of the work. During the centering operation the drills are automatically withdrawn twice, so as to clear them of chips, and allow oil to enter the drilled hole. Each spindle has a maximum feed movement of 7/8 in., which may be reduced by a regulating lever to 7/16 in. with any variation between to suit the size of drills or the nature of the work. The machine may be run through its cycle of operations by hand to check the set up. A crank handle fitting the squared end of a shaft in the change gear box is supplied for this purpose.

In order to hold the drilling depth to any dimension desired, adjustable stops R are provided which are mounted on the head and bear against the ends of the work to limit the forward movement of the spindles. In certain cases it is necessary to have the center holes the same distance apart regardless of variations in the length of work. For this purpose the adjustable stops are positioned to engage lugs on the drill heads, thus holding the spindles to a predetermined forward movement.

The drills are driven by individual motors mounted in the head and geared so as to provide a speed of 1,200 or 1,800 r.p.m. Changing gears or locking the spindle for the removal of drills is easily taken care of by knobs on the top of the drill heads. The magazine A, and work supports are mounted on the head castings so that it is only necessary to move the heads along the bed to accommodate various lengths of work. The sides of the magazines are easily adjusted for diameters of work as they are slotted and held by simple square head screws.

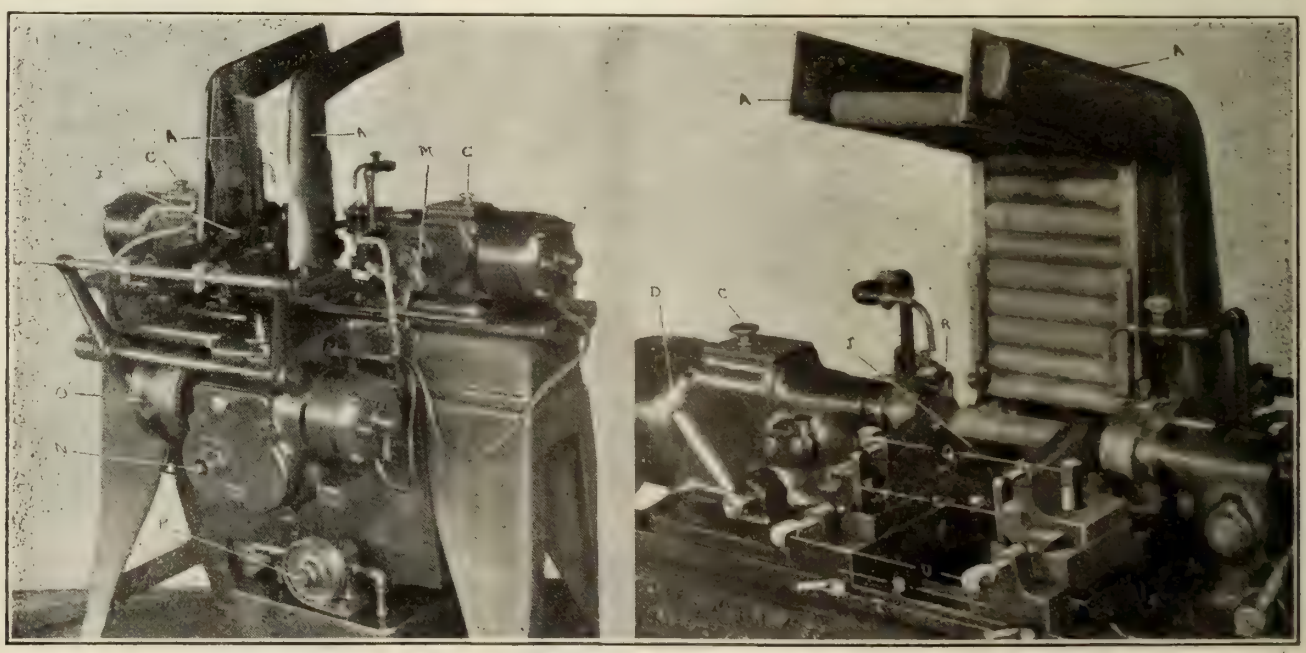
The work is supported by V jaws during the centering operation. These jaws are provided with adjusting screws so that they may be set to any desired diameter while an automatic compensating arrangement takes care of minor variations in the diameter of the work. The work is clamped in the V jaws by transfer plates J on the slides which remain in contact during the drilling. By simple adjustments of the V jaws it is possible to drill holes out of center on one or both ends, such as holes for driving pins used in grinding, short oil holes, etc. Facing or chamfering tools may also be used in place of drills if desired. Different transfer plates taking care of various diameters of work, are easily mounted in place. Four sets of these plates cover the range of the machine.

Oil is supplied to the drills from a geared pump P running at a constant speed. The tank is located underneath the bed and the oil drains into it from all parts of the machine including the work box. The work box is taken off for cleaning and removing the finished work. The work pieces are ejected directly into the box and when the box is removed while the machine is running a deflector hinged on the bed can be latched in position to catch the work.

The machine has a capacity of work from ¼ in. to 1½ in. in dia., and from 2½ in. to 18 in. in length, with a net weight of 1,020 lbs. It requires a floor space of 4 ft. 6 in. by 2 ft. 6 in. This machine centering has been developed and placed on the market by the Pratt and Whitney Co., New York.

TILTED THREADING MACHINE

A new type of threading machine, in which the spindles are tilted and which can be adapted to both internal and external threading has just been placed on the market. The machine has a capacity when working on internal threads of ¾ in. dia. U.S.S. threads. It is equipped to provide both forward and reverse movements to the spindles. The six spindles are located at an angle of 30 deg. from the vertical to facilitate



Left: Rear view of the automatic centering machine. Right: Close-up of magazine and feeding mechanism.

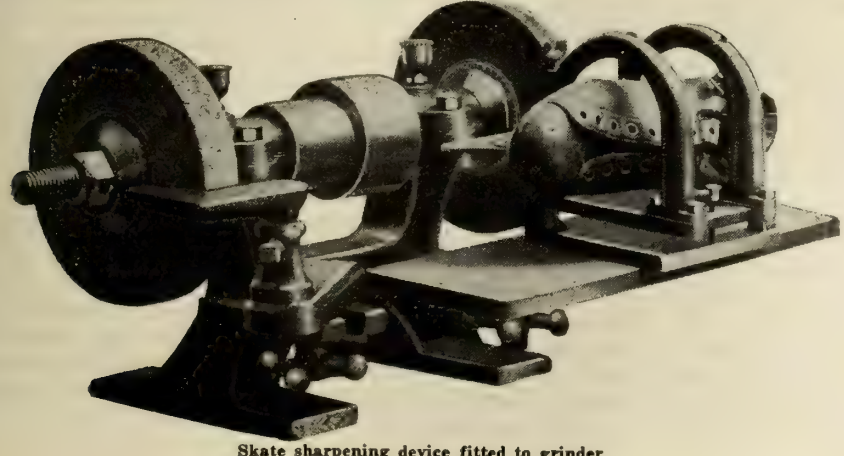
likewise permit of using self-clamping jigs. The tapping spindles are provided with spring collets. Four changes of speed are provided with double speed reverse action automatically taking place when desired depth of thread is reached. The design permits of continuous operation as the arrangement of the work-holding fixtures permit of loading six while tapping is proceeding on the other six. The work is moved up to the taps by means of a foot treadle. The row of jigs can be moved along the bed so as to bring them in line with the tapping spindles. Oil is forced individually to each spindle. Bronze bearings are used throughout and thrust points are fitted with ball thrust bearings. It is claimed that production may be maintained at the rate of 1,500 pieces per hour. For outside threading the capacity is threads of 1 in. dia. Self-opening dies are used and machine can be adapted to cutting either right- or left-hand threads. The machine requires a floor space 66 x 41 in., and is made by the Holmes Engineering Co., Oshkosh, Wis.

ROTARY MILLING MACHINE TABLE

A rotary table, controlled by the regular feed levers of the machine, including the traverse, has been developed recently and placed on the market. The table is driven from the feed drive shaft through a telescopic shaft and two pairs of steel bevel gears that drive a 2½-in. steel worm meshing with a 20-in. worm wheel. The sixteen regular feeds may be used to operate the rotary table. The design of the mechanism makes it impossible to engage more than one power feed at a time. These controls make the attachment especially serviceable for continuous milling. The table is 24 in. in dia., but work of a larger size may be accommodated. The table is graduated the entire 360 deg. These table attachments are made by the Toledo Milling Machine Co., Toledo, Ohio.

SPECIAL BENCH GRINDER

The accompanying illustration shows a skate grinding attachment that has been fitted to a grinding wheel and placed on the market recently. It is intended for use in small machine shops for service throughout the winter months. The device is designed so that the skate may be ground either while attached or detached from the boot. The holder may be moved freely along the table which insures uniform grinding of the skate blade. This device has been developed by the Prescott Emery Wheel Co. of Prescott, Ont.



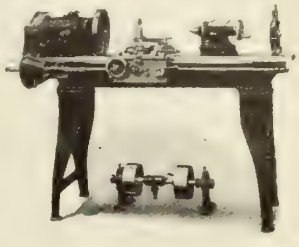
Skate sharpening device fitted to grinder.

SIX SPINDLE CHUCKING MACHINE

An automatic machine that is particularly serviceable for handling a product that can be held in a chuck, as castings, forgings and short pieces of bar stock, and which requires a number of separate and distinct operations as turning, facing, chamfer, form, drill, bore, ream, thread or any other regulation lathe work, has just been placed on the market. The machine will handle five pieces of work at one time. There are six spindles, five always in working position, the sixth being in the loading and unloading position. When a finished piece reaches the loading position the machine automatically stops so that inattention of the operator will not cause work to make a second cycle of operations. The machine may be started immediately, work proceeding on the five working spindles while the sixth is being reloaded. As many as twenty-one cutting tools may be used at the one time. The machine has a speed range of from 28½ r.p.m. to 440 r.p.m., divided into 24 speeds. This permits of any spindle being run at any one of three different speeds. In addition to the variable spindle speeds there are 17 different feeds for the cutting tools. It is possible to arrange the spindle and feed speeds so as to give the greatest productive speed for the work in hand. A hole of small diameter can be bored at a high rate of spindle and cutting speed while at the same time the outside circumference might be turned at the best speed for that operation. Tool holders are designed to receive standard tool bits. Machine requires a floor space of 93 x 46 in. It is operated by a 5 h.p. motor; carriages and tool slides are fitted with rapid traverse or reverse. The machines have been developed by the Baird Machine Co., Bridgeport, Conn.

12-INCH ENGINE LATHE

The small engine lathe here described has just been placed on the market. The lathes may be supplied either with the cone pulley or the all-steel geared head, both of these being driven either by belt or motor. The cone pulley headstock is of the enclosed type which rigidly supports the two bearings and maintains alignment. The back gears are extra wide face and thoroughly protected. The single pulley drive geared headstock is fully enclosed and the steel gears run in an oil bath. Six spindle speeds are provided for. The driving pulley of the geared headstock is fitted with a friction clutch operated by a shifting bar extending the length of the lathe. The hollow spindle is extra large and made of carbon steel. All bearings are accurately ground to size and run in phosphor bronze adjustable and easily replaceable bearings of more than ample load capacity. These lathes are equipped with positive tooth faced reversing clutches, by means of which both the longitudinal and cross feed and the direction of the head screw may be instantly reversed without engaging or disengaging gears stopping the lathe, shifting belts or reversing the spindle rotation. The tailstock is of improved offset type. Tailstock spindle is of large diameter, accurately ground and fitted to reamed hole. Tail centre is self ejecting. The carriage, which is extra wide and heavy, has a long bearing on the bed, and is gibbed both in front and rear. The compound rest has an exceptionally wide bearing with adjustment to compensate for wear. The circular base is graduated. All gears in the apron are of steel and bronze bushed. Apron gearing is so arranged that operator may readily shift from thread cutting to the use of either the traverse or cross feed without the shifting of gears. All lathes may be furnished with gap beds which are well braced and proportioned to be as strong in the gap as in any other portion of the bed. The gap bridge is accurately located by taper pins and rigidly held by cap screws. Special motor and countershaft support are provided for motor-driven cone headstock. A swing bracket assures constant tension in the drive belt. In addition to the regular equipment the lathe may be furnished with taper attachment, milling attachment, etc. These machines are built in 10, 12 and 14-inch sizes and are made by the Oliver Machinery Co., Grand Rapids, Mich.



12-inch engine lathe.

Export By Canadian Lines

IS EXPORT traffic moving as freely as it should through Canadian ports and via Canadian lines? There is said to be a much larger Canadian tonnage moving through American ports than should be. Canadian lines, it is reported, are refusing to meet competitive conditions and are strictly adhering to rates established by the Atlantic Conference, whereas certain lines operating out of New York and other American ports frequently name rates materially lower.

Manufacturers are making some investigation in the matter. If existing conditions make route via American ports more favorable, steps should be taken immediately to place the fullest kind of information before the Government. The primary object behind the development of Canada's Merchant Marine was the encouragement of export business. If American rates are so very attractive as to draw patronage from this side of the line, then a readjustment of some kind would appear to be necessary.

The day when Canadian raw materials had to be exported to the other side to be converted into finished products, and then resold in Canada to be retailed, is gradually passing. The day when Canadian ports and shipping should be able to handle Canadian export products, has surely arrived.

An Industrial Incubator

BELLEVILLE has an industrial incubator. It is a building in which space is made available to enterprises in their infancy. There they install their machinery and establish business headquarters. Whether the concern is of local origin or comes from outside, is of no significance. The building represents the combined interest of a number of business men in the development of the city industrially.

A similar "beehive" was opened years ago in Walkerville, where several important enterprises had their Canadian origin, gradually outgrew available space, and are now located in larger plants throughout the city. Others took their places in the building. The idea probably originated in Walkerville, and was so successful that Belleville has adopted it with good results. The proposition has never had to go begging and the companies now occupying the structure represent a fine addition to the city's roster of manufactories.

This is a plan that lends itself to the encouragement of legitimate enterprises looking for location. With such a building at its disposal, the city's cards are immediately upon the table. It does away with the necessity of a standing policy on free sites, fixed assessments and bonuses that are too frequently held out as inducements to prospects looking for much and eventually giving little. Here is a central location, with all conveniences and facilities. If the enquiring firm means business, it is a comparatively easy matter to place it in the way of securing essentials to machinery installation and early operation.

Such a building is adapted to the ambitions of most municipalities. It enables small industries to develop on a minimum cost basis, and very often does away with the necessity for expensive separate structures, temporarily at least. Having once found its stride, and realized that its development entitles it to larger quarters, an industry may build to suit its requirements, thus making room in the incubator for another infant.

Railroads May Order Cars

PROSPECT of early buying activity on the part of the railroads will be welcome news to industry generally. There are reports to the effect that orders for about six thousand box cars are in process of development as a starter. In fact, manufacturers declare that they have had preliminary enquiries as to available materials and it is felt that the long deferred buying urge is about to take actual shape.

There are many plants throughout the country that owe their existence to the fact that Canadian railroads are like those of other countries in one particular at least, and that is in essentials of upkeep or efficiency. These plants were developed on the idea that where there are something like 200,000 cars in actual use, some are junked each year, additions have to be made annually to replace these and to meet the growing requirements of the country. Yet, some plants have been running on short rations because the railroads are not buying.

A box car requires several tons of castings and forgings, a refrigerator car calls for a large amount of heavy galvanized sheetings and other materials, to say nothing of heavy steel plates, bars, lumber, paint and special apparatus requiring the employment of much skilled and unskilled labor. It needs no imagination to see that a wave of economy on the part of the railroads cannot be long drawn out without leaving some industries high and dry.

Car shortages are in sight. In Canada the roads are said to be shy, to-day, about 8,000 cars. In the United States, the shortage is placed at 130,335 cars. This immense carrying deficit makes it a difficult matter to secure prompt return of Canadian cars in the United States or to effectively resist the leakage of Canadian cars to the other side. Some action may be taken by manufacturers to see what can be done about it, but in the meantime it would seem to be good policy to build more cars.

Improved Shipping Conditions in Steel Centres

Cars Do a Little Better Than Take Care of Production—Situation By No Means Well In Hand—Decline in Canadian Pig and Ingot Production—Montreal Advances Boiler Tubes

SEASON DECLINE IN GALVANIZED SHEETS

SHIPMENTS are running a trifle above production, is the report from Pittsburgh. Steel accumulations are beginning to move slowly. Canadian industry has been handicapped by delayed shipments. One large concern, having a contract for construction of refrigeration cars and for repair of a large number of American freight cars was confronting a shut-down a few days ago. No material was coming forward. Today, conditions have improved, but the service is far from normal. Canadian mills depending upon daily arrivals of certain material report that difficulties appear to multiply rather than grow less. Some of the embargoes have been lifted on American roads and those existing are now regarded as relatively unimportant.

Ingot production continues on a 70 per cent. operating rate. Ingot production in Canada for September was 35,787 as against 59,201 in August. Pig iron production in the same month was 24,974, while in August the amount was 27,123. September production was less than that of the same month last year by 40.8 per cent. There are said to be 16 idle blast furnaces in Canada at present. Steel Company of Canada are contemplating the reconstruction of their B furnace and expect to blow it in on foundry iron Dec. 1.

Many of the American steel mills are reporting labor shortages, owing to high wages paid by contractors who are rushing buildings before inclement weather arrives. Advance of wages has been discussed, but the feeling seems to be that winter conditions will produce adequate hands for inside work. Another wage advance at present seems ill-advised. There have been no changes in prices on bars and plates at American mills, and Canadian warehouse prices remain firm. There has been a seasonal readjustment of price on sheets, owing to larger supplies coming into the market from Old Country producers and also from American mills, and also as the result of slackening activity in roofing operations. Black sheets, No. 28, are now quoted at $5.10; blue annealed, $4.20; galvanized, $6.40. Hamilton mill prices on premier galvanized sheets are $5.40 to $5.60. In non-ferrous ingot metals there have been notable price changes recently. Owing to speculative activity in the British market, tin has advanced until Canadian dealers who were quoting $37.00 a week ago now announce a price at around $40.00; spelter, used in galvanizing, has advanced from $8.75 to $9.50, while lead is now quoted at $8.75, an advance of one and a quarter.

Machine tool demand shows some improvement, but conditions here still reveal a somewhat spasmodic trend. Activity in woodworking machinery reflects better business in the furniture factories and sawmills. The report that the railways are making some enquiry looking to the placing of orders for about 6,000 freight cars is a matter of considerable interest to many departments of industry.

Toronto

November 1, 1922.

LAST quarter business in Toronto iron and steel market, should it maintain October's record, will give a fairly satisfactory ending to a year that has been marked by many retarding influences. Not the least of these have been labor troubles which caused some apprehension as to supplies and shipments of material. Car shortages are now developing on Canadian lines, and may prove a handicap to industry generally. There has been no railway buying apart from that arising from immediate needs, but reports among manufacturers indicate that there is likelihood of a loosening up on freight car construction for both National and C. P. R. lines. This would bring activity to a large number of plants that have been carrying on with more or less difficulty. The building activity has been the basis for considerable business, but this is bound to slacken with the arrival of cold weather. Already there has been a slight falling off in galvanized sheets used for roofing purposes. Price reductions in this department may be said to be seasonal.

Iron and Steel.—Business continues to show a good volume, and prices remain steady. Supplies of sheets have improved by reason of the fact that fair quantities have recently arrived from the Old Country, and shipments from the United States have come through in fair volume. Black sheets, No. 28, quoted last week at around $5.50, are now at $5.10; blue annealed sheets, No 10, are down from $4.50 to $4.20, while galvanized sheets, No. 28, are down from $6.60 to $6.35 and $6.45. Hamilton mill price on premier galvanized sheets is $5.40 to $5.60. This adjustment of price is generally made at this time of the year. It will also probably have the effect of moving stocks that jobbers have no desire to carry

There is some activity in boiler tubes, and while Montreal announced an advance of one cent a foot, some Toronto jobbers have as yet taken no action, giving as one reason the fact that new stocks have not yet arrived. However, an advance of about 10 per cent. is imminent. This would bring 2-inch lapweld, now $18, to $19.80; 2¼-inch to $22; and 3-inch to $30.25. Toronto dealers are quoting the following prices on sheets and bars:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 15	3 25
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 50
Sheets, blue ann., No. 10		4 20
Canada plates, dull, 52 sheets		5 75
Canada plates, all bright		6 75
Galvanized Sheets, No. 28	6 35	6 45

Pig Iron.—Demand is largely from hand to mouth, the feeling having developed that further reductions are in sight. Price for domestic remains at $36.30. There are reports that British pig iron is being marketed in Eastern Ontario towns at from $33 to $35. Some trouble is reported in connection with the use of imported pig, in that certain grades have become mixed in transport and, when foundries have no means of chemical analysis, the chance they are taking is obvious. However, this is not a general condition, but might better be attributed to accident in shipment. Buffalo reports No. 1 foundry at $30.50, and malleable at $31. Steel Company of Canada will blow in its foundry furnace about Dec. 1.

Old Material.—This market maintains a decided lack of feature. No large quantities are moving in any direction, and it is reported that furnaces are holding off for lower prices. This seems to be a natural tendency in view of easing prices on pig iron. Shipping difficulties are also apparent in the movement of old materials. Dealers' average buying prices:

Copper, light	9 00
Copper, crucible	11 50
Copper, heavy	11 50
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	7 00
Red brass turnings	7 00
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00

Non-Ferrous Metals.—Tin, spelter and lead have shown activity during the past week. Tin, subject to speculative influences in England, where something like a corner exists, has advanced from $37 to $40.00; spelter, in demand for galvanizing is quoted at $9.50, an advance from $8.75; while lead is quoted at $8.00, an advance of one-half. Current prices:

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	40 00
Lead	8 00
Spelter	9 50
Antimony	8 50
Aluminum	22 00

Notwithstanding the advance in welded steel pipe by American mills, no advance has been announced by the Canadian mills. Difficulties in obtaining supplies of skelp, owing to car shortages, have multiplied if anything.

Demand for brass and copper products begins to show the advance influence of the Christmas season. Some firms in these lines have already added to their working forces.

Steel shipments from American centres have shown no improvement during the past few weeks. The situation is not likely to be improved by the shortage that is developing on Canadian roads.

Montreal

November 1

MARKET conditions during the present week show no change of any importance except in regard to boiler tubes. Due to the strong demand which has lately prevailed resulting in the depletion of stocks to a large extent, coupled with the extended delay of obtaining replenishment from mills, prices have advanced by about a cent a foot and may be subject to another advance of the same extent in a short time. The demand for all products keeps up to the level of the past few weeks and as predicted, October will go out as one of the banner months of this year.

Black and galvanized steel sheet situation has firmed up a little lately in the Pittsburgh district and an advance of around $2.00 per ton has gone into effect. Blue annealed steel sheets have also been advanced to the same extent. Deliveries are a disappointing feature in regard to these commodities from U. S. mills. The Leading Interest is now indicating 3 to 4 months' shipment on new orders. Some of the independents can improve upon this but their prices are on a higher level.

The last direct boats for Montreal this season will be leaving British ports within the next ten days and, therefore, importations of sheet products from the Old Country mills will be curtailed until the opening of St. Lawrence navigation next spring. As the additional cost of freight via the winter port will offset all the advantages of buying in that market, the demand will, therefore, be directed almost entirely to sources of supply in the U. S. Local prices:

Iron bars, base	3 15 to 3 25	
Steel bars, base	3 15 to 3 25	
Reinforcing bars, base	3 15 to 3 25	
Steel hoops	....	4 00
Tire steel	3 25 to 3 40	
Spring steel	....	7 00
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes	....	3 40
Sheets, black, No. 28	....	4 65
Sheets, blue, ann., No. 10	....	4 00
Canada plates, dull, 52 sheets	....	5 50
Canada Plates, all bright	....	7 00
Galvanized Sheets, No. 28	....	6 50

Non-Ferrous Metals.—Ingot metals are very strong, especially tin, zinc, spelter and lead. The advance in spelter will probably mean higher prices on galvanized sheets. Copper is dull and unchanged. Local prices:

Lake Copper	17 50
Electrolytic Copper	17 25
Castings, Copper	17 00
Tin	39 50
Lead	7 50
Spelter	9 50
Antimony	7 25
Aluminum	22 00

Pig Iron.—Montreal and district seem to be in a rather quiet condition just now, buyers feeling their way and purchasing for immediate needs only, being under the impression that prices may show some decline in the near future. Your correspondent understands that some fairly large business in the way of car construction is being negotiated and it is hoped that orders will be placed shortly which will give an impetus to the Canadian iron and steel trade, but as yet matters have not progressed sufficiently far to warrant any definite statement in this connection.

Algoma, No. 1, car lots on tracks, nominal quotation		38 65
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	40 50	....

Machine Tools.—Speaking of the machinery demand here, a dealer states: "We find there is a decided improvement in demand for mill supplies in this territory. Also there is an upward tendency in the price as evidenced by advice of advance in prices received from several different manufacturers. This advance applies not only to supplies but also to machinery. As regards the demand for machinery, there have been more orders placed lately for new tools than for some time past and every condition seems to point to still further improvement."

Another firm reports as follows: "There has been a slight improvement in general conditions in this district. This has been due, to some extent, to the expansion in the pulp and paper business. The new mill at Three Rivers will be operating by the end of this year, and other paper mills are making additions to their plants. Some of the manufacturers have recently advanced prices, but there is still a tendency among some of the dealers to cut prices. This condition exists when the material is in stock."

Pittsburgh

November 1.

CAR SUPPLIES for shipping steel products from mill have increased somewhat more, and shipments on the whole are at least fully equal to current production, while a portion of the steel previously accumulated at mill has been moved. In individual cases a mill may be unable to ship all its product, but in the industry as a whole the shipments have been running a trifle above the production. There are still some embargoes against shipments to certain points, but the embargoes are now relatively unimportant.

Mill operations have undergone no material change since late in September. Ingot production is about 36,000,000 or 37,000,000 tons a year, representing approximately a 70 per cent. operating rate in the steel industry as a whole. Supplies of coal and coke are no longer the dominant factor in regulating the production, and have not been for several weeks. In the majority of cases the state of order books is the controlling factor in operations, there being several important exceptions. One is in pipe, for practically all the pipe mills have demands upon them, chiefly for shipment against orders placed at various times in the past, in excess of what they can meet, and some of the mills are definitely allocating their shipments, in accordance with the quantities of steel the respective customers have previously received from them. Another exception is the sheet operations of the American Sheet & Tin Plate Company (Steel Corporation) which have been below the order book requirements for a long time. In this case the chief factor is shortage of steel, although there is also some shortage of labor.

Another Wage Advance?

There are, in fact, labor shortages at many of the mills, not enough usually to restrict production, but enough to cause much inconvenience. The chief cause is the high rates bid by contractors having buildings they wish to complete within contract time or before the weather gets bad. The matter of making another wage advance, following the 20 per cent. advance that became effective September 1, has been canvassed by some producers, particularly the Steel Corporation. Action has been held in abeyance on account of the possibility that the approach of winter would cause men to leave outside employment and seek mill and furnace employment. It is commonly recognized that another wage advance at this time would be economically unsound.

The majority of the rail mills are now rolling and shipping rails against the large contracts recently booked. This business was secured by the medium of announcing that an advance in price from $40 to $43 would be made at the beginning of October, and that meanwhile contracts would be accepted at the old price, for delivery up to July 1, 1923. Previous reports as to this business did not bring out very clearly the important fact that it was stipulated in the contracts that the deliveries should be at a practically uniform rate from date of contract to the middle of next year. Thus the object of the maneuver, to obtain

winter rollings, was fully accomplished. It is obvious that the idea of there being an acute shortage of steel, in general, is quite out of date, as the railroads were not anxious to begin receiving and paying for rails so soon.

Prices Unchanged

Basis prices for steel products, i.e., prices that include no delivery premium, are unchanged, and indeed there has been no particular change in them since early in September with the exception of the advance in welded tubular goods of about $4 a ton, made under date of October 19, as noted in last week's report.

Premiums on early deliveries of bars, shapes and plates have been diminishing for a month or more and in the past week have almost disappeared, for now it is only on quite small lots or very prompt shipment that any premium needs to be paid. Fairly good deliveries can be secured at the basis price of 2.00c. It is reported that, in one case, 1.95c has been done on bars.

In the matter of sheet prices there is a curious condition. Until a week or so ago all independents were on the basis of 3.50c for common black, or higher, 3.60c being obtainable on fairly early delivery, while there were instances of 3.75c being done. The week's developments include the divergent reports that one or two mills are now seeking attractive orders at 3.35c, which was the price of the Steel Corporation until it became sold out for the year several weeks ago, and that one large tonnage order has been placed at the extreme price of 3.75c, shipment in ten days. Just where the sheet market is going to land is a question. The American Sheet & Tin Plate Company will probably announce a first quarter price within the next fortnight but there is no basis for guessing whether this will be the old price of 3.35c or will be an advanced price, and even when the corporation does make its price it would not follow that the independents would sell at it. The policy of the majority is to get more than the corporation price if they can, and cut the corporation price if they deem it personally advantageous.

Wire remains at 2.45c, nails at $2.70, tin plate at $4.75, hoops at 2.90c to 3.00c, according to width and gauge, and merchant steel pipe at 66 per cent. basing discount.

Stiffening in Coke

After its sharp break from $12 to $8, Connellsville furnace coke has been relatively steady in the past week, only softening a trifle. Odd lots can be picked up at $7.50 while a fair sized lot, particularly for regular shipment over a week or two, would probably command $8. Far from admitting that the prompt market is likely to decline farther, coke operators are talking $9 on contracts to the end of the year, suggesting that there will be a fresh car shortage in December on account of the weather, putting up the spot market from its present level. Blast furnacemen show little disposition to concur with this view, largely no doubt because they find it rather difficult to sell small lots of pig iron for prompt shipment and practically impossible to sell for extended delivery. Hence, instead of its being a question, as formerly, of each idle merchant furnace getting into blast as soon as it could acquire a coke supply, there is a question whether all the furnaces now in operation will continue. Bessemer, quotable at $33, valley, a week ago, has since sold at that figure, while the $30 quotation on basic of a week ago is likewise supported, by one or two sales. Foundry iron is off $2 to $30, on light sales. Prices quoted are f.o.b. valley furnaces. For a time there was practically no valley iron, and the Pittsburgh market was based on what it would cost to bring iron from Buffalo or other points.

INGOT PRODUCTION DECREASED

Production of Canadian steel in September declined by 23,373 long tons from the output of 59,160 tons in August to 35,787 tons in the month under review. The cumulative output during the first nine months of 1921 was 477,588 tons, as compared with the production of 334,835 tons in the corresponding period of the present year. The closing of the steel plant at Sault Ste. Marie accounted in large measure for the decrease in production during September.

Output of basic open hearth ingots for further use declined from 56,997 tons in August to 33,815 tons in September, a decrease of 23,182 tons or 40.7 per cent. A small quantity of electric steel ingots for further use, amounting to 124 tons, was reported for September while none was made for direct sale.

Total production of ingots was less than the output of the corresponding month of last year by 20,540 tons, or 37.7 per cent. The production in the first nine months of 1922 was 319,943 tons, while that of the corresponding period of the previous year was 459,960 tons representing a decrease of 30.4 per cent. The production of steel castings also suffered a decline. The total output in August was 2,204 tons which decreased to 1,848 tons in the month under review. The decline amounted to 356 tons or 16.15 per cent. An opposing tendency developed in connection with basic open hearth castings of which the production increased from 208 tons to 837 tons. On the other hand the output of Bessemer and electric grades declined considerably.

OPERATIVE CONSTRUCTION OF HAND LEVERS

(Continued from page 35)

is nevertheless used for the purpose of replacing a hand lever. In this construction it is desired to operate by hand a connecting bar M for starting or stopping the machine. This is done through the medium of a rocking lever N which pivots on a stud P; attached to the upper end of lever N by a stud Q is a bar R, this bar passes through holes in brackets at S and T. The object of this bar is to permit an operator to take hold of the bar at any point along its length and by pulling to operate connection M through the medium of the lever N, thus controlling the operation of the machine. It will be evident that this is a very neat arrangement to permit of quickly controlling a machine operation from the various positions where an operator is apt to be, it being a design particularly applicable to long machine construction.

A very powerful foot treadle action is shown by Fig. 8. In this instance the foot treadle is indicated as A and this is made in part with a boss extension at B. The foot treadle is supported on the shaft C in a bracket D held to the base of the machine. Attached to this foot treadle at B are two connecting links E, one on each side of the lever, the lower ends being connected to the foot treadle while the upper ends are tied together by a stud F, with nuts and washers thereon. Through this stud passes a connecting rod G, the upper end of which is attached to such units as it is desired to operate. When pushing down this foot treadle the action becomes more powerful as the end B of the lever passes through the lower portion of the arc of the radius H. The action of this foot treadle is such that when the operator starts to push on it this pulls down rod G very rapidly, while at the lower end of the stroke where great power is required G is pulled down only slightly with a long action at the end of the foot treadle.

Many very good examples of foot treadle and lever design are brought out in punch press construction and Fig. 9 shows some of these. In the centre is shown a plain foot lever press in which the lever A is pushed back with a swinging movement thus forcing down ram B and multiplying the power greatly as the lever pivots at C. This foot lever hangs in such a manner that the weight of the lever causes the foot treadle to return to its starting point by gravity. The view to the right shows another foot press action where a foot lever D pivoted at E is connected at F to a connecting bar G which is in turn connected at H to a lever J, which operates the ram K of the press, the pivot for this last lever being at L. It will be noticed in this connection that lever J has a counter-balance weight M to return the foot treadle to its starting point, while a number of pivot holes are provided at E and H to vary the stroke and leverage exerted by the foot treadle D. In the lower left hand corner is shown a foot lever N having a counterbalancing weight P attached thereto; this weight takes the place of a spring, the lever pivoting in a bracket Q while a rod R connects the lever to the operative mechanism above.

(To be continued.)

SELECTED MARKET QUOTATIONS

News From the Industrial Field

E. B. Eddy Co., Hull, Que., are considering the location of a branch factory at Sault Ste Marie, Ont.

Clifton Mining Company, at Porcupine, Ont., have installed a steam plant as an auxiliary to electric power.

Ontario Metal Products, Toronto, have moved from corner of King and Jarvis Sts., to Room 16, at 84 Victoria St. Frank C. Annette is sales representative.

St. Lawrence Supply Co., 167 Commissioner St., Montreal, will handle the packing line of Quaker City Rubber Co., Philadelphia, for the province of Quebec.

Night Hawk Peninsula Mine at South Porcupine are assembling machinery in connection with their new mill. Concrete substructure has been completed. Equipment will be installed next spring.

A new carrying device for the lifting of heavy iron weights or boulders has been invented by Thomas Ashton, a railway shop employee of Edmonton. It consists of a double adjustable chain and clamps permitting either attachment to a steam crane or carrying on a bar.

British Empire Steel, according to a report from Sydney, N. S., will expend $50,000 on plant to increase galvanizing capacity in the wire mill. Demand for domestic and export fence material is increasing. The present capacity of the mill is about 60 tons a day. Proposed additions to be completed early in the New Year will double the output.

St. John, N. B.—Dr. W. H. Collins, director of the Geological Survey, Department of Mines, on his return from a three weeks visit to the various field parties who are at work surveying the mineral industry of Nova Scotia and New Brunswick, is most optimistic. He reports new coal beds the existence of which was unsuspected, and deposits of oil shale in both provinces, associated with coal measures. They are not yet being mined, but constitute the basis of an important future mining industry.

Calgary, Alta.—One of the greatest drives in the history of the Eau Claire Lumber Company, of Calgary, has just been brought to a successful conclusion by the driving of 5,000 000 feet of spruce logs, sixty-five miles down the Bow River from Ghost River, where the logging operations of the company are at the present time conducted. The saw mills of this company are turning out finished lumber at the rate of 50,000 feet a day, and there is already a stock of something like 6,000,000 feet of dressed lumber on hand in the yards.

Canadian-American Alloy Corporation which took over the plant of the Electric Steel and Metals in Welland, has not yet developed productive activity. Eventually this company will, it is said, turn out heavy railway castings and other steel products.

Dominion Iron and Steel Company, Sydney, C. B., recently shipped 1,800 tons of pig iron for Philadelphia and 400 tone of wire for New York. The rods will be re-shipped to Vancouver, B. C., by rail. The pig iron shipment is the first of its kind in several years to be shipped to the United States.

As reflecting general trade conditions ninety-two ocean and coasting vessels were berthed in the wharves at Montreal. This does not take into account vessels from the great lakes. Since the opening of navigation the port has been visited by 1,033 ocean and coasting steamers as compared with 964 vessels arriving during the whole of last season.

Flint Varnish and Color Works of Canada, have erected at West Toronto a plant for the manufacture of lacquers and pyroxylin products from basic raw materials. The plant includes technical laboratories necessary to demonstrate their products in a practical way to manufacturers. The line includes metal lacquers, wood lacquers, bronzing liquids, split leather solutions, waterproof belting cement.

Plant for the reduction of bituminous coal into coke at Sydney, N. S., is being considered by the Government as a safeguard against recurrent coal strikes in the United States. The supply from the proposed Sydney station would be designed especially for central Canada. A similar station may be established in the west if necessary, but it is calculated that British Columbia or Alberta coal either in its natural form or as briquettes, will not come east of Winnipeg.

With a view of co-operating with any municipality in Canada that is desirous of acquiring industries, the secretary of the Federation of British Industries, has issued a statement which says, in part: "Where any overseas Government, Dominion or Provincial, is anxious to promote industries within its borders, we here can probably be of considerable assistance. There are many firms in this country who are following the establishment of home industries overseas with interest. I can assure you that there is an amount of interest taken in the Canadian market which would surprise some critics of the British manufacturer if its full extent were known."

D. M. Fraser, Corman Engineering Co,. Toronto, announce that they have purchased the plant and equipment of the Chapman Double Ball Bearing Company, Sorauren Avenue Toronto. They have taken over the entire Chapman line and added to their regular products. They are going to move shortly into the plant on Sorauren Avenue, but in the meantime have some men there working on demand for Chapman products.

The construction of a new addition to the plant of the Howard Smith Paper Mills at Cornwall, for the manufacture of bleached soda pulp, will likely be started shortly, according to an announcement made at a directors' meeting held last week. Canadian requirements for this product have so far been imported. The new plant when completed will have a capacity of 15,000 tons per year. The soda pulp will be used for mixing with sulphite pulp to go into the manufacture of certain grades of paper.

ADVISES 60-DAY COAL SUPPLY

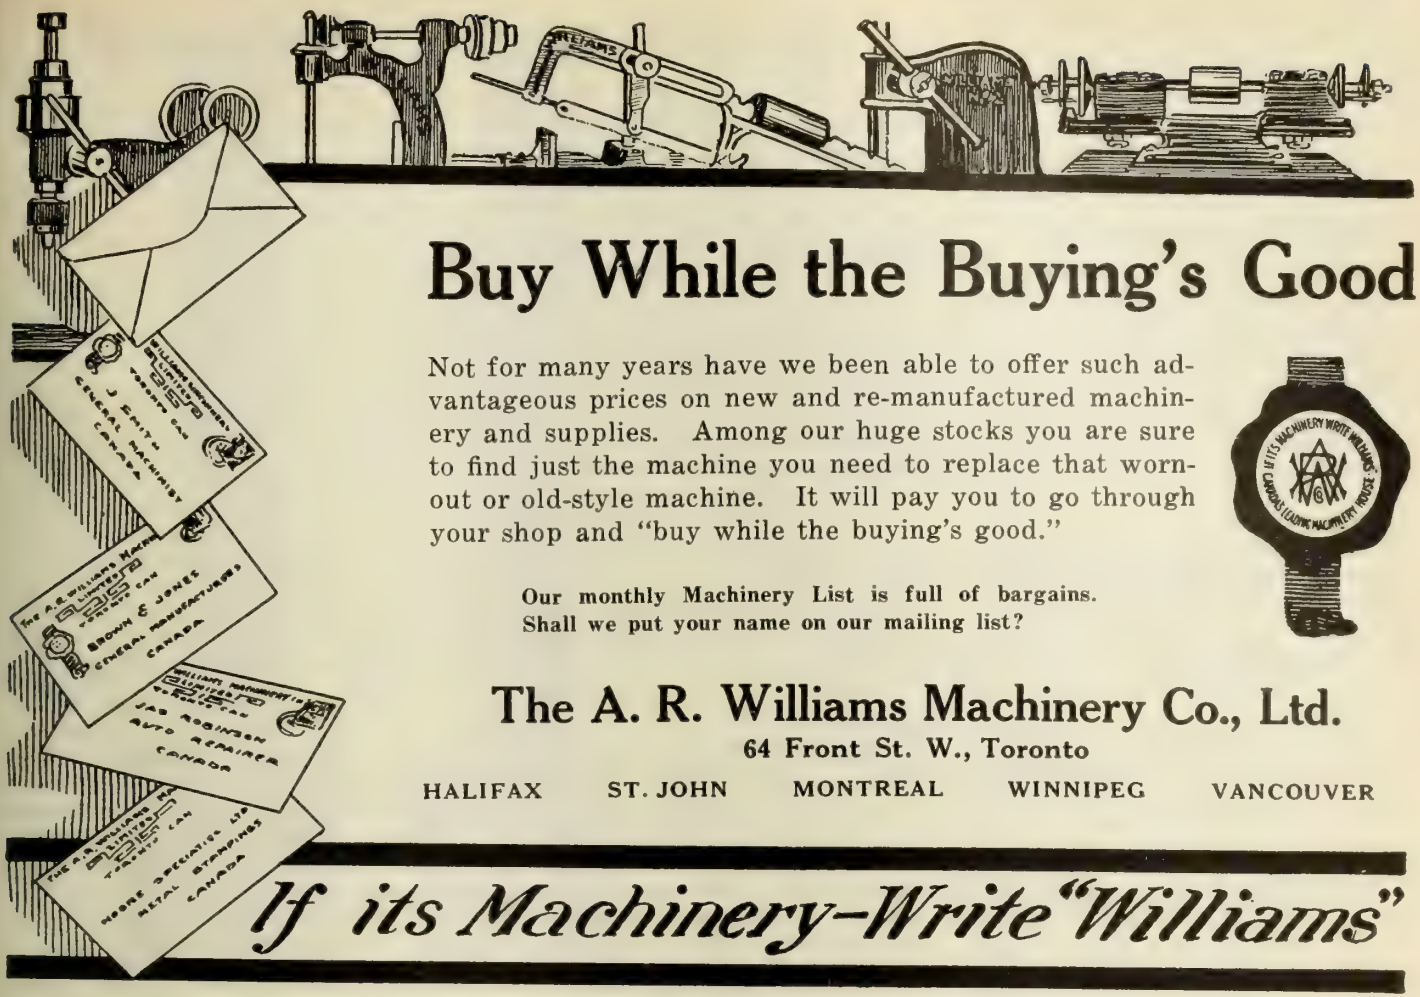
At a meeting of purchasing agents a few days ago. F. J. Carson The Harris Abattoir Co., Toronto, discussed the coal situation in relation to industrial requirements as follows:

"Production appears to have struck a temporary level. The weekly output is now about 9,700,000 tons. This is about the same tonnage as reported at our last meeting in September.

"In the last report I stated that production was increasing and that prices would drop a little, but also drew to your attention, that there was a possibility of a car and motive power shortage. Production did increase slightly and prices drop a little, but the car shortage came sooner than expected and production is now curtailed considerably.

"Central Pennsylvania reports a daily shortage of 800 cars and West Virginia about 50 per cent. of their normal supply. The car shortage, which means less production, and the winter coming on should have a tendency to increase prices and I would suggest covering at once. Steam slack is selling around $3.50 to $4.00 per ton at the mines. Steam run of mine $3 65 to $4 00 per ton; steam lump $4 35 to $4.75 per ton; gas slack $4.00 to $5.00; gas run of mine $4.75 to $5.25; gas lump $5.00 to $5 75.

"It is still a question of transportation, and I would advise carrying a 60-days' supply until we can see improvements on the railroad."



Buy While the Buying's Good
Not for many years have we been able to offer such advantageous prices on new and re-manufactured machinery and supplies. Among our huge stocks you are sure to find just the machine you need to replace that worn-out or old-style machine. It will pay you to go through your shop and "buy while the buying's good."
Our monthly Machinery List is full of bargains.
Shall we put your name on our mailing list?

GOOD ROADS AND INDUSTRY

That the development of the automotive industry is closely related to increased mileage of good roads in every province, is established in a bulletin recently issued by the Department of Railways and Canals. It is pointed out that the grand total value of automobiles, supplies, accessories and repair parts manufactured in this country increased from $101,196,706 in 1919 to $137,420,351 in 1920. The capital investment necessary in the production of these goods amounted in 1920 to $89,183,306, an increase of 57 per cent. over the year preceding. Over 14,500 persons were engaged in the making of these products, and this group of industrially employed earned nearly $23,500,000 in 1920. There are in Canada seventeen motor vehicle manufacturing plants of which ten make passenger vehicles and seven make trucks; and the motor vehicle supply plants number in all sixty-two. It is said that no less than eighty-five different occupational activities or classifications of skilled labour are necessary in the assembling and completion of one motor vehicle. The making of 94,000 passenger and commercial motor vehicles in Canada in 1920 therefore helped largely to increase the skill as well as the pleasure and profit of a large group of our citizens.

But to the above total of persons dependent upon the automotive industries should be added automobile dealers and their employees. The Automotive Industries Association of Canada report that there were in 1920, 5,522 automobile dealers, employing 43,094 persons, to whom $56,022,200 were paid in wages. Public garages, repair depots, accessory supply stores, and gasoline stations swell the number, so that the employed and their dependents concerned with the manufacture, sale and service of motor vehicles in Canada total approximately a half-million persons.

The total mileages of roads in the various provinces, under control of counties, townships, rural and urban municipalities and provinces are given as follows:—Alberta, 88,500; British Columbia, 15,424; Manitoba, 68,000; New Brunswick, 13,547; Nova Scotia, 15,188; Ontario, 64,198; Prince Edward Island, 3,650; Quebec, 43,877; Saskatchewan, 135,000; Total in Canada 447,384.

BELLEVILLE DISPLAYS PRODUCTS

Belleville.—The made-in-Belleville Exhibition was held in the Belleville Armories four days, October 24-28. His Honor, The Lieutenant-General speaking at the official opening, complimented Belleville in general and the Chamber of Commerce in particular on the number of exhibits and care taken in their preparation. About 70 Belleville firms had exhibits among which were the following in engineering and metal-working lines:

Grand Trunk Belleville shops, exhibit of apprentice drawings, and other work.

National Castings, Ltd., steel, semi-steel, grey iron and aluminum castings.

Marsh Engineering Wks., boilers, contractors' mining and hoisting machinery.

Canadian Alemite Products Co., lubricating systems for industrial and motor car uses.

Canadian Industrial Alcohol Co., alcohol for industrial purposes.

Elliott Machine Co., wood-working machinery; Fruit Machine Co., canning factory machinery; Weed Harvester Co., agricultural machines; Steel Co., of Canada, steel products; American Optical Co., optical goods; Belleville Electric Stampings, electric specialties; Springer Lock Mfg., Co., and Belleville Hardware & Lock Co., builders' hardware; International Burr Co. metal burrs.

The armory was divided into eighty booths all of which were taken up by local concerns. The exhibition was staged by the Chamber of Commerce with the purpose of showing the variety of industrial activities of the city. An elaborate program of entertainment was arranged in connection with the exhibit.

SIXTEEN BLAST FURNACES IDLE

Effect of coal scarcity and transportation difficulty is shown in the fact that the production of Canadian pig iron in September declined 7.92 per cent. from the output of August, according to the Dominion Bureau of Statistics. The August tonnage was 27,123 as compared with 24,974 tons in September. The production was also less than that of September, 1921, by 40.8 per cent. A comparison of the cumulative production during the first nine months, 1922, with that of the corresponding period last year shows a decrease from 457,157 tons to 275,989 tons or 39.6 per cent. The Steel Company of Canada blew in a furnace at Hamilton, after certain repairs; the Algoma Steel Company banked one furnace, while at Sydney one furnace was blown in by the British Empire Steel. At the present time the active furnaces are two at Sydney, one at Hamilton and one at Sault Ste. Marie, a gain of one furnace over the previous month. This leaves 16 blast furnaces idle.

Another development was the slight increase in the several grades of iron produced for sale. The production of basic pig iron increased from 6,577 tons in August 1921, to 7,991 tons or 21.5 per cent. The September production intended for this purpose was also higher than in September of last year by 58.14 per cent. The foundry pig iron produced for sale increased from 6,296 in August to 6,895 tons in September. The output of malleable iron for sale also rose from 281 tons in August to 1,096 tons in the month under review.

The production of ferro-alloys dropped slightly from 1,864 tons in August to 1,834 tons in the following month. The cumulative production in the first nine months of 1922 was 15,178 as compared with 18,698 tons during the corresponding period of the previous year.

ENGINEERS IN ANNUAL RE-UNION

At the fourth annual re-union of the Engineering Alumni Association of Toronto University, Oct. 27 and 28, engineers from all over the Dominion and the United States assembled to renew friendships and visit once more the scenes of their college days. The programme as arranged by the executive of the Alumni, was a complete one, festivities opening on Friday evening with a dinner dance. Saturday morning the year meetings were held at Varsity, all the classes from away back in the eighties down to last year, being well represented.

At the annual dinner held in Convocation Hall, Capt. C. E. MacDonald proposed the toast to the University of Toronto. In replying, Prof. A. T. DeLury of University College, made reference to the Literary and Scientific Club of olden days and said that the Alumni Association was rapidly forming closer bonds between School and the rest of the University.

In replying to the toast to the engineering profession, Dr. A. C. Humphreys, president of the Stevens Institute of Technology, Hoboken, N. J., laid stress on the point that students should be properly prepared in the essentials before commencing an engineering education. Prof. H. E. T. Haultain of S. P. S. proposed the Silent Toast, which was followed by "The School," by W. E. Douglas of the Class of '02, and replied to by Dean Mitchell of the Class of '92. General Mitchell appealed to the Alumni for scholarships saying that it was only by the individual and co-operative efforts of the Association that scholarships could be provided, and that it was in this respect that the alumni could best help the students of to-day.

Should Piston Rods Be Ground?

WHEN the question of the installation of new equipment comes before the management of manufacturing plants to-day, the modern executive requires to be shown the advantages that will be derived by the proposed change of practice before deciding on the best machine for the purpose. Owing to the many factors to be considered it is frequently desirable to exercise a reasonable degree of caution before committing one's self on the adoption of any particular style of equipment.

While there is still some difference of opinion regarding the most efficient method of truing both new and used piston rods, extended tests seem to favor the grinding process. As an instance of the study that has been given to this phase of railway practice the following extract of an article in the Railway Mechanical Engineer may be of interest:

"Notwithstanding the almost universal approval of piston rod grinding, the innate caution of railroad men regarding new devices was strongly illustrated in a large railroad shop recently where it was proposed to install a mchcine to grind piston rods instead of continuing the older method of turning and rolling them. Those who hesitated to install the new machine said that it must first demonstrate its superiority in a comparative test. Accordingly, a new piston rod was turned and rolled as accurately as possible. This rod was then carefully mounted in a piston rod grinder and ground, with the abrasive wheel just lightly touching the rod. The grinding operation was then stopped and observers noted that more metal was removed at certain places on the piston rod than at others and in some places the abrasive wheel did not touch the rod at all.

"Micrometer calipers checked the accuracy of grinding both as regards taper and roundness of the rod. The fact that more metal was removed by grinding at certain places than at others proved conclusively that the rod, as rolled previous to grinding, was not a true cylinder. This was evidently due to the fact that the rod was non-homogeneous, being softer in some spots than in others, with the result that the roll depressed these soft spots unduly. The grinding machine, on the other hand, exerted hardly any pressure on the rod and removed as much metal from the soft spots as the hard, producing a true cylindrical surface.

"In the days of wick packing the accuracy of piston rods did not make so much difference, but now that metallic packing is used almost universally it is evident that this packing cannot hold steam and last for any considerable length of time unless piston rods are accurately round, smooth and, practically speaking, without taper. That these qualifications are best obtained by the use of modern piston rod grinding machines is evident from the many ground piston rods now in daily use and giving satisfactory service."

QUEBEC'S INDUSTRIAL PROGRESS

Quebec ranks as the seventh largest manufacturing centre in Canada. According to the latest census, there are 424 manufacturing establishments of all industrial activities centered in the city. More than half, however, are small in importance, but nevertheless, thorough in equipment. These establishments represent over ninety different lines of production. The principal industries are engaged in the manufacture of boots and shoes and leather tanning of which there are forty-seven. The output of these boot and shoe factories is scattered all over Canada, and principally sold to Ontario and Western jobbers. Machine shops, boiler and other steel and iron plants, come next with forty establishments, and next in order are food producing factories, 27 in number. There are 20 woodworking concerns, which include the manufacture of doors and other essentials in building construction and the manufacture of packing cases, boxes, etc.

The capital invested in Quebec industries, according to statistical information, amounts to $36,927,434.00, employees on salaries and wages, $11,500; salaries and wages paid out per annum $6,979,516.00; cost of raw material used $16,067,679, and value of finished products $38,265,277.00 The population of Quebec City has increased from 68,840 in 1901 to 116,850 in 1921, and the total value of assessable property which was $26,397,309.00 increased to $114,327,947 in 1921.

These figures serve to demonstrate the growth of the city in an industrial sense, and the fact that it is well equipped to make further progress as an important factor in Canadian manufacturing as a whole.

It Was Just A Matter of Grinding

The same set of Thread Chasers cut these two threads.

Observe what a clean cut the Chasers gave on this open hearth stock after they had been correctly ground. Note how neatly the Chasers curled out the chip. Before given the right form of grind, the Chasers simply pushed out the stock.

How To Grind Thread Chasers

Instructions for the Care of Thread Chasers are very completely given in a 27-page booklet published by us.

The Book Is Free

To those having the care of Thread Chasers. It is printed and distributed with the hope that the rules given will be followed, and if they are, it will be the means of an inestimable saving of time, money and trouble.

If you have anything to do with the care of Thread Chasers, ask us for the book. Although there is no charge for the book, it is full of value. It will cost you the price of a postage stamp only, and will save you trouble, increase your value to your employer and save a lot of money that is needlessly wasted in time and scrapped work.

Hamilton Industries Report Conditions Improving

Steel Company Will Blow in Second Furnace by Dec. 1—Reconstruction Nearing Completion—Using Some Magnetite Ore—Better Demand for Machinery—Railways May Order New Cars

HAMILTON.—Steel Company of Canada, expect to have their B blast furnace going again on foundry iron by December 1st. Their A furnace was blown in early in October on basic pig for the company's steel requirements. This furnace has a daily capacity of three hundred tons. With two furnaces going the company's daily requirement in coal is something like 2,000 tons. The Hamilton plant is now operating on 50 per cent. capacity. This will improve according as supplies of coal become more easily available. It is scarcity of fuel that is not only curtailing the operation of this and other plants, but is impeding the operations of customers and hence affecting the demand for products.

During the recent reconstruction of one of their blast furnaces, Steel Company engineers were confronted with the task of replacing the foundation. This was found to be necessary as the result of serious fissures in the concrete mat which underlies the substructure of brick and concrete. This mat of concrete has a depth of 10 feet and a diameter of about forty-five feet. Below this there is piling to a depth of about 60 feet. This is necessary, as the site is of made ground. The cracking of the mat was unforeseen and its replacement, together with that of the heavy base on which the furnace stands, has been an undertaking of some proportions. The furnace proper and all of the steel work, produced by the John Inglis Co., Toronto, is practically completed.

While the Steel Company are using American ores from the Mesabi range, they have, from time to time, made extensive experiments with Canadian magnetite ores. At the present time, they are using a quantity, about 10,000 tons, of the briquetted magnetite ore produced by the Moose Mountain Mine, in the Sudbury district. This mine has produced many thousands of tons of ore that is said to run over 66 per cent. pure iron, about 4½ per cent. silicon and from .012 down to .006 phosphorous. Some of this ore, during the war, was shipped as far south as Tennessee. Under normal conditions it does not compete with the American ore. It is claimed, however, that it meets commercial requirements.

The Steel Company frequently receive samples of ores from different sections of the country when outcroppings occur. There are many of these; in fact prospectors in the north country state that they know of immense outcrops that they have never taken the trouble to stake. As a rule, samples sent in reveal small percentages of iron. One recently received from Broughton, Que., showed 38 per cent. It was, however, a very small sample, and not taken as is desirable from different sections of the vein. The Steel Company, naturally, are anxious to promote discovery and development of Canadian ores, have done much experimental work, and have encouraged exploration looking to the location of adequate bodies.

Hamilton firms report preliminary enquiries with reference to proposed construction of new rolling stock for the railways. For the Canadian National lines, it would appear that plans are gradually taking shape for the erection of 3,000 freight cars and 700 refrigerator cars, while the C. P. R. may shortly call for 2,000 new freight cars. Developments looking to the actual placing of this business is being watched with considerable interest as it will mean activity in many plants where there is not much doing at present. In this connection, a manufacturer points out that, with about 200,000 cars as a total on Canadian lines, practically nothing has been coming through of extensive repairs, as was regularly the case in prewar days. From latest information received, something like 14,000 "bad order" cars have been reported, and as for the two-week period ending Oct. 1, a shortage of about 8,000 cars was reported. October, however, is always a heavy month, and it will probably be found that the shortage will run above that figure. The fact that the railways have been doing practically nothing in repairs or replacements means much to many industries.

Ford-Smith Machine Co., Hamilton, report, in recent business, the sale of a miller to an Alberta colliery company, which has been installing new machine shop equipment and of two grinders—one a 20-inch water tool type, and the other a 14-inch heavy type—to the Imperial Oil Co., for their proposed Calgary plant.

Brown-Boggs Co., Hamilton, report improved inquiry for punching and shearing equipment, and that the year to date shows a much better record than last year. Toronto office reports the sale of one of their machines and several enquiries during the past few days.

National Steel Car Company, Hamilton, who are said to have considerable work on hand in the repairing of cars for American roads, are reported to be finding it difficult to obtain supplies of material as the result of freight congestion and embargoes on the American side of the line. It is understood that specifications in connection with such a contract, require that, where possible, the materials used be from American mills and shops. About the only Canadian factor in such a contract, it appears, would be the labor.

A. T. Enlow, Dominion Sheet Metal Corporation, Hamilton, reports a strong demand for galvanized sheets and that, up to the present time, no serious difficulty has developed in obtaining shipments of black sheets from American mills. As to the price situation, he looks for a fairly even level for the next few months. with very little movement up or down. The Hamilton mill price on premier galvanized sheets is $5.40 to $5.60. In marketing material of this kind, as between Hamilton and Toronto for example, the motor truck is being used to some advantage in making daily shipments. Many firms are now using this means of transportation where quick delivery is called for.

Smart-Turner Machine Co., Hamilton, report the following recent sales: Two No. 4 double suction centrifugal pumps for the Abso-Pure Ice Co., Hamilton; few small triplex power pumps, ordered by Department of Marine & Fisheries, for delivery to the Dominion Lighthouse Depot, Prescott. A No. 4 belt-driven centrifugal pump, ordered by H. F. Routley, Toronto, for quarry service near Caledonia; one 4½ x 2¾ x 4 duplex, packed-piston pump, to Standard Paving Co., Lindsay; a pair of 8 x 10 x 12 simplex vacuum pumps; an automatic feed pump and receiver equipment with motor-driven centrifugal pump and two motor-driven centrifugal circulating pumps for the Essondale Asylum, Vancouver, B. C., and a 5½ x 6 triplex power pump for Vipond-North Thompson Mines, Timmins, Ont.

Dominion Steel Foundry Co., Hamilton report that two six-ton electric furnaces which they installed two years ago, replacing the ordinary open-hearth furnace, have given satisfactory service. Six heats a day are possible where formerly two and one-half were obtained, and the result has been a more uniform grade of metal. The Hamilton foundry reports a fair amount of business in sight. A branch foundry at Watervliet, N. Y., also equipped with steel furnace, has been exceptionally busy. Activity in car construction would create a larger demand of heavy castings for which the Canadian plant is equipped.

ATKINS SAWS

METAL CUTTING

Present Conditions

Don't let present-day conditions worry you: everything is fundamentally sound. More economy is being called for, use

Atkins Metal Cutting Saws

Conditions are such that quality and quantity production is essential. The use of Atkins AAA Non-Breakable Hack Saw Blade and Frames, Circular Metal and Slitting Saws, Hot Saws, Cold Saws, Kwick-Kut Hack Saw Machines and Blades and Metal Band Saw Machines, will assure you of efficient, economical operation and give you quality and quantity production.

USE NATIVE ORES TO SOLVE FUEL PROBLEM

Hon. Harry Mills, Minister of Mines for Ontario, is of the opinion that some substitute for coal should be evolved for the more economic operation of industries. He felt confident that such a fuel would be obtained and that one of the greatest existing industrial problems would be solved thereby. Addressing a special meeting of the Board of Trade at Sault Ste. Marie, the Minister of Mines also emphasized the benefits that must accrue to the country generally from the development of low grade iron ore fields of Northern Ontario.

J. A. McPhail, the chairman at the meeting discussed the feasibility of a native blast furnace, based upon the use of low grade ores such as are easily available. He pointed out that the great cost in connection with the steel plant there was the assembling of raw material. For this reason, he said, the largest and best steel plant in the country was only partially operating. "For every dollar there is spent in Canada for wages, two dollars are spent for transportation," he said, "and if the iron ore which is right near our doors could be utilized by our plants think what a difference it would make to that industry. At the present time coal and iron is shipped from the United States almost entirely." Mr. McPhail said he had learned that the ideal steel could be manufactured from a fifty per cent. mixture of magnetic and siderite after they had been treated, and both of these ores existed here in good quantity. In a few years he prophesied the mining and treating of iron ore would be one of the leading industries. If the iron ore fields could not be developed without obtaining a bonus he thought it would show the development could not be done economically, and as Toronto papers prophesied, developments would be stopped. If ore could be proved up in sufficient quantities, however, to warrant the securing of large capital to back the move, Mr. McPhail said the situation would be different.

STEEL BUSINESS OUTLOOK GOOD

John Mackrell of McGregor & McIntyre, Toronto, reported upon iron and steel conditions to a recent meeting of purchasing agents as follows:—

"The American steel mills at the present time are booked very heavily, with no indication of any letup in receipt of orders. The railroads are the heaviest purchasers, 1,000,000 tons of rails having recently been ordered for delivery the first half of 1923. Orders are coming in regularly for new equipment for railroads, as well as repairs to cars and other rolling equipment.

"Requirements for oil business are also extensive, 100,000 tons of pipe having recently been placed by one concern for pipe line.

"Steel requirements for general building in the States are good, for auto business requirements are considerably more than anticipated earlier in the year.

"The disappointing feature has been the requirements for implement business, but present indications are improving in this respect.

"Delivery of steel at the present time is seriously hampered by embargoes and lack of railway equipment to handle the business, due to recent railway strike. Car shortage for steel is also caused by coal requirements. On this account many mills have large tonnages piled up waiting for cars, and have had to curtail output.

"Prices have been upward for sometime with no indication of retrenchment. The Corporation price at present is $1.85 base Pittsburgh, but independents are demanding from 15 to 25 cents per 100 lbs. more for plates than other shapes. Blue annealed sheets are quoted by the Corporation at $2.50; black sheets, $3.-35, and galvanized $4.35, but Independents are somewhat higher, but delivery much earlier

STEEL TUBING

CLOSE Joints and Welded Steel Tubing for Bedsteads, Trolley Arms, Agricultural Implements, and all other manufacturing purposes, reliable quality, uniform in size, 14 to 20 gauge, 3-8 inch to 2 inch outside diameter.

Herring-bone Cut Gears

Roll Pinions With Special Long Teeth

GEAR DATA FOR YOUR NOTE BOOK
Cut this out,—more coming later

FROM THE HAMILTON GEAR & MACHINE CO., TORONTO

Pinions mounted on the necks of rolls which are adjustable for centre distance, must of necessity work at variable depth of mesh.

The resultant back-lash is unavoidable, but continuous smooth action in one direction can be assured by using Double Helical gears. With spur pinions on enlarged centres a point is quickly reached where the tooth contact is not continuous and the action is jumpy. This need not be so with correctly proportioned Double Helicals.

Note that when teeth mesh only part depth the load is concentrated on that part and wear increased.

GOODELL-PRATT

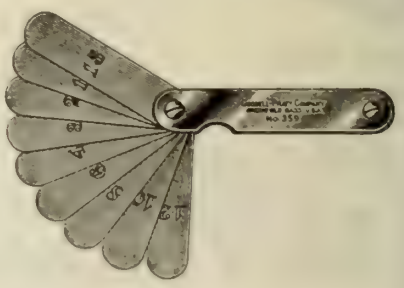
1500 GOOD TOOLS

If you can find More Accurate Tools Buy Them

We say this because we don't believe you can find any machinists' tools of greater accuracy. But we don't want you to take our word for it; we prefer to have you subject Goodell-Pratt precision tools to the most exacting tests in comparison with any other standard brands.

Take Center Gauges, for instance: Every Goodell-Pratt Center Gauge is made of spring tempered crucible steel accurately ground and graduated. Each Center Gauge is lapped in the V's and tested to make sure that it is a light tight fit.

Look at Goodell-Pratt Feeder Gauges: no oversize, undersize or uneven leaves are included.



"Tools for the Toolmaker" shows all these good tools. Write for it.

THROUGH WITHOUT CHANGE!

How it may be applied to handling material

FROM one corner of a factory floor to the other; from one department to another; from building to building; between any two points in your plant WITHOUT CHANGING OR REHANDLING THE LOAD. That is the service provided by a Shepard hoist operating on a Transfer Crane and suitable monorail track.

The hoist operating on the crane covers the width of a bay, and the crane covers the length—all points are accessible. The crane may be run to a position where it connects with monorail track, and the hoist and load can leave the crane and travel along the monorail track to any designated department.

The possibilities of this type of equipment are almost unlimited. Our engineers have helped in laying out systems for many and diversified businesses, and they will gladly assist you. Call upon them.

STEWART

Triple Purpose Furnace

Combining three Standard Stewart Furnaces—No. 0 Crucible Furnace for cyanide and lead hardening; No. 28 Oven Furnace for high-speed and carbon steel; Stewart No. 3 High Speed Steel Furnace. This Stewart Triple Purpose Furnace provides a complete compact plant, covering practically the whole range of heat treatment of metals. The units may be operated singly or any two at a time. Compact, convenient — saves steps for the toolmakers.

STEWART

Industrial Furnaces

Stewart Furnaces are more than an assembly of steel plates, refractories, valves, etc. They are an effective combination of practical heat-treating experience and furnace engineering of unusual skill. In design and build they reflect over 25 years' actual experience of heat-treating problems.

There is either a Standard or Special Stewart Furnace to handle every requirement efficiently and economically. Here are a few:

Annealing
Billet Heating
Brass Melting
Carburizing
Cyanide Hardening
Drop Forging
Galvanizing
High Speed Steel Hardening
Lead Hardening
Oil Tempering
Pre-Heating
Rivet Heating
Rod End Heating
Soft Metal Melting
Spring Hardening
Tinning, etc.

There's a Stewart for every purpose.

Why Don't You Write?

HARDLY a week passes that Canadian Machinery does not receive copies of this paper returned by the postal authorities because of the change in firm names or the address of some whose names are on the mailing list. Sometimes complaints reach us of the non-delivery of mail matter. It is not till the receipt of such complaints or the return of the paper, as the case may be, that we obtain any knowledge of the changes or removals of persons or firms. The adoption of the co-operative spirit on your part by notifying changes would make things a good deal more pleasant for both parties. The MacLean Publishing Co. want their mailing list to be in such shape that they will be able to render the perfect service to their subscribers. There is a lot of valuable trade matter mailed by this company and if you don't receive it—well, the fault is entirely yours.

MADE IN CANADA

Is your belting efficient under all conditions?

THE Main Belting Company has perfected a method of making either Leviathan or Anaconda endless in a factory. The belts produced by this method are positively unequalled. They are scientifically proportioned to the size and character of the load to be handled. They are cured under tension, as is every foot of belting we make, and the result is a belt of exactly the right length, in which stretch is at a positive minimum, with flexibility and driving power at the maximum. These belts can be installed with absolute confidence.

The ACME

¾ Inch Six-Spindle Semi-Automatic NUT TAPPER

THE design of this machine will readily be appreciated by observant engineers and mechanics. It is of substantial dimensions and is exceptionally strong where strength is needed to withstand the most arduous service—yet it is quick and easy in operation.

Each spindle is equipped with Automatic Lifting Service, which lifts the spindle to allow the automatic feed to place the nut under the tap.

Spindles have counterweights to facilitate handling and to prevent breakage of taps by spindle starting the taps in the nuts too suddenly. All gears and pinions are cut and made of good quality steel.

These are but a few of the features of this machine. Our catalog, which we will send upon request, contains a complete description.

Built for Arduous Duty It is Quick and Easy in Operation

MILL REQUIREMENTS

English Millboard

Are you acquainted with the superior quality of our Gray English Millboard. If not send for samples. Test it and compare it. Supplied in three thicknesses—2/16″, ¼″ and 5/16″.

Asbestos Millboard

This class of millboard can be used for a variety of purposes. It offers the most economical protection against fire in buildings of all kinds. It is used extensively for backing other materials. It pays to use only the best quality—we have it.

Excello Roofing

This is the highest grade roofing we can procure. Made in medium, heavy and extra heavy weight. Fully guaranteed. Where a permanent roofing is required we strongly recommend Excello.

Asbestos Sheathing

Put Asbestos Sheathing in the dangerous places in your shop. Our brand is thoroughly fire-proof, tough and durable and can be relied upon to give long and satisfactory service. It is inexpensive.

Small Tools of All Kinds for Machine Shops

Jewel Roofing

Made in light, medium and heavy weights of first-class material. Jewel Roofing is our next grade to Excello.

Asbestos Shingling

A large percentage of fires start from sparks falling on the roofs of buildings. Roofs with asbestos shingles are immune from fire starting from this cause. Our shingling meets all requirements.

Asbestos Fibre

(Liquid Cement)

This rubber-like adhesive is made of the finest asbestos fibre, creosote and specially selected oils. Easily applied to any kind of roof—metal, gravel or composition.

Crown Roofing

Made in light, medium and heavy weights, is lower priced to meet requirements of those who are using it for more or less temporary purposes

Buying made easy

By grouping together these manufacturers of Special Machinery, Gears, Gauges, Dies, etc., we are making buying easy for you. Here you have a directory of the firms who can fill your requirements on any of these lines. When you are in need of any of the above, consult the firms listed here

CANADIAN MACHINERY
Buyers' Directory
143 University Ave. - - Toronto

$5 May Save You $500 or $5,000!

You work hard for the dollars you save. Properly invested they can be made to work hard for you. But they must be properly invested.

If you feel the need of a guide to show you how to invest your money to bring you the biggest return consistent with safety; to show you how to avoid the pitfalls of investment; you need THE FINANCIAL POST.

It will give you a personalized investment service. Its articles every week will tell you what you want to know about investing. Its discussion of current business and national problems will give you a new angle on economic and political questions. You will have too all the privileges of the Investors Inquiries Department. You may ask as many questions as you like about your own investment and financial problems—the standing of your broker, and the analysis of particular securities, insurance problems, etc. This service is free to all readers.

Stop losing money on bad investments. Invest $5 now where it may save you $500 or $5,000. Pin a $5 bill to this ad. (or your letterhead), write your name and address and we will send you THE POST for one year (52 issues).

THE FINANCIAL POST 143 University Ave. Toronto

If what you need is not advertised, consult our Buyers' Directory and write advertisers, listed under proper heading

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Mechanical Goods of Proved Value

The right machine or supplies for your particular requirements; experienced men who can give you definite information regarding your special problems—both may be found at the nearest branch of Canadian Fairbanks-Morse. Fairbanks-Morse products, designed by our own engineers and made in our own factories, have built up a world-wide reputation for reliability.

Canadian Fairbanks-Morse agencies comprise the world's leading manufacturers of mechanical goods—of machines and supplies that have the fullest endorsement of the largest number of users.

Here Are Some of the Well-known Lines we Handle:

- Fairbanks Valves
- Brown & Sharpe Machine Tools
- McDougall Lathes
- Gisholt Turret Lathes
- South Bend Engine Lathes
- Landis Threaders
- Graton & Knight Leather Belting
- Yale Chain Hoists
- Esterbrook-Allcard High-Speed Drills
- Norton Grinding Wheels
- Dick's Balata Belting
- Fairbanks-Morse Motors
- Durabla Packing

Each department is ready to extend the fullest co-operation in the solution of your problems because it is in charge of experienced men who know how best to meet your particular requirements.

Old Man Johnson And His Sled Waste Oils

Are you paying $1,200 a year to old man Johnson? He is that unnecessary man who fetches and carries oils and varnishes from a wasteful storage house to the different points of use. Having him around means that you are wasting oils, for depreciation is fast when air reaches them.

And give old man Johnson a productive job. Install Bowser equipment. Stop this waste.

Barrels can then be immediately and completely emptied and returned for credits or sold. New purchases are checked on receipt by the Bowser gauge. Oils and varnishes stored indefinitely without evaporation or deterioration in quality. Minimum insurance rates are assured. Labor in handling is saved. There is no spillage or waste.

Write for Bulletin C-13 and let us quote actual examples of money saving installations of Bowser equipment for finishing oils and varnishes.

Bowser Equipment is MADE IN CANADA by

S. F. BOWSER & CO., LTD.

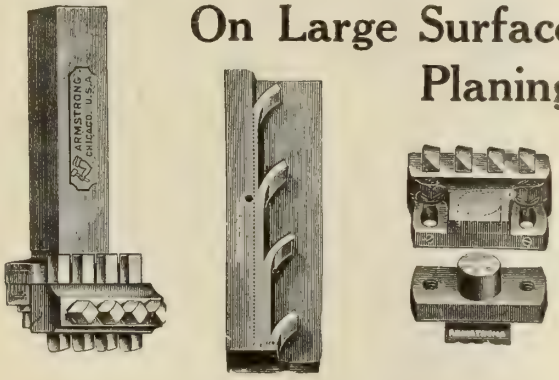
Saves 75% of Your Time On Large Surface Planing



The Armstrong Gang Planer Tool

is specially adapted for surfacing large castings. Its graduated head (which permits speed and ease in setting to any desired feed) makes possible the greatest speed on metals of varying degrees and hardness.

With this tool a planer will carry with ease a feed and depth of cut much greater than is possible with an ordinary tool and with less tendency to "break out" at the end of the cut.

Write for Catalogue.

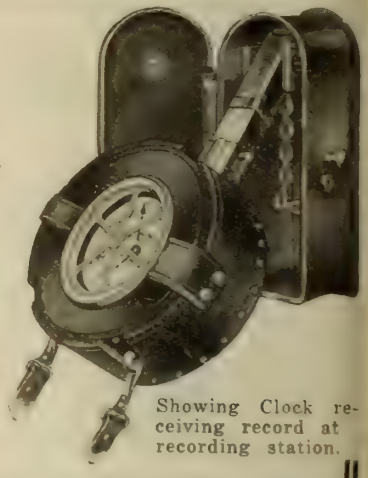
Watch Your Watchman!



Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful. There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.
Send for Catalogue C.M.

Producing Accurate Gears By Multiple Shaping

Interchangeable Arbors Facilitate Output—Cycle of Operations Entirely Automatic—Micrometer Adjustment for Cutting Depth —Machine May Be Adapted to a Variety of Purposes

MULTIPLE shapers are built in two distinct types, up-stroke and down-stroke, each adapted to its own particular service. The advantages of this method of cutting gears arise from the fact that two work arbors are used, changes being made at the completion of each arbor full of gears.

When cutting gears by this method the blanks are first placed on an arbor as shown in Fig. 1. The ram is then elevated sufficiently to allow the tapered shank of the arbor to be inserted in the socket of the ram. The arbor is secured in position by means of a draw-bolt passing through the centre of the spindle. This draw-bolt is operated by means of a power-driven clutch controlled by the machine operator. The clutch is equipped with an automatic overload throw-out, which operates when the tension has reached a predetermined amount. When the arbor is secured the ram is lowered by power and automatically stopped when it has reached the working position. The machine is then started by the operator pressing an electric push button. The entire cycle of motions necessary for cutting the teeth is automatic. This gives the operator an opportunity to prepare another set of blanks on a second arbor, so that a minimum amount of time is required when recharging the machine. An electric brake is used for stopping the machine. The operator again temporarily elevates the ram to the charging position, reverses the draw-bolt lever which ejects the arbor, replaces the second arbor of blanks and proceeds as before. The entire time of cutting occupies from one to four minutes, depending on the face width of the blanks and depth of tooth being cut. The time required for stopping the machine, changing the arbors and starting again, is about one minute, thus making the total cycle of operations in a little over two minutes for an average.

The arrangement of the multiple shaping cutters and the method of operations is clearly shown in Fig. 3, where the sheet metal chip guard and top plate have been removed to disclose the interior mechanism. The tool head consists essentially of a flat steel disc, 30 in. in dia., provided with a hole at the centre and a number of radial grooves cut in the face in which the tool bits are arranged like the spokes of a wheel. The feeding movements are imparted to the tools by an annular sectional cam ring. As the gear blank is reciprocated past the cutting tools, the latter are gradually fed in to the full depth of the tooth. At the completion of each stroke of the ram, and before the next cut begins, the gear blank is indexed a space equal to the circular pitch, thereby presenting a different tooth space to each cutter from the one which made the preceding cut.

Uniformity of Tooth Shape

After the tools have been fed in to full depth, they are held stationary in that position while the cutting process continues until the gear has indexed one complete revolution thereby giving each tool an opportunity to take one last cut on each tooth. This final complete index insures a uniformity of spacing of the teeth in the gear equal to that of the indexing mechanism. This uniformity of the tooth form is secured even though the tools themselves may be far from uniform, for it is at once apparent that if any tool is longer or wider than any other tool, even though it be only a thousandth of an inch, that portion of it which is longer or wider will take one last cut on the corresponding portion of each tooth in the gear, thereby eliminating any variation which may have been caused by previous cuts. By this process of finishing all the teeth of a gear with a single finishing tool, this machine attains great accuracy and the speed is multiplied by the number of tools in operation on the gear blank at one time.

To facilitate production duplicate tool heads are provided for each machine, so that one is operating while the other is in the tool room having the tools resharpened and put in condition for relieving the working set. Special clamping devices provide for rapid and accurate changing of cutter heads.

The tool bits, a group of which are shown in Fig. 4, are rectangular in shape

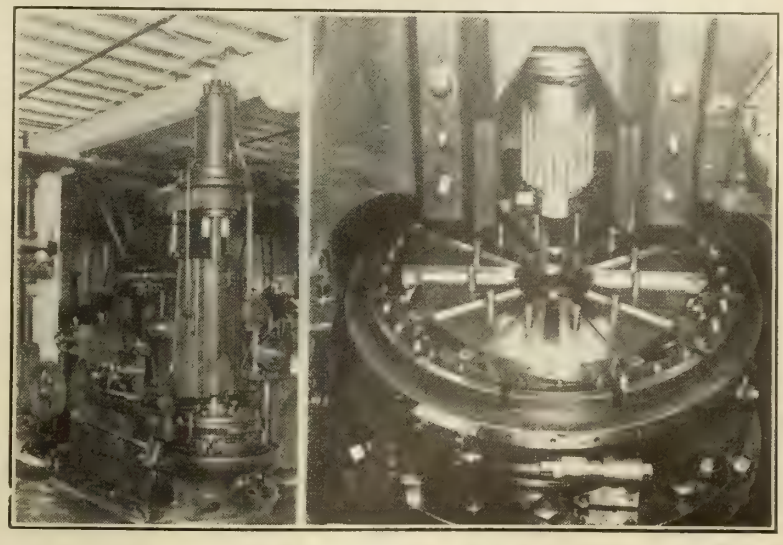

Fig. 2.—Left: general view of shaping machine. Fig. 3—Right: top plate removed, showing arrangement of cutters.

Illustrations and data through courtesy of Stevenson Gear Co., Indianapolis, Ind.

except the lower side which is in the form of a V. The gear tooth profile is formed at the inner end of this tool and is backed off to permit sharpening without changing the form. The outer end of this tool rests against a spiral cam surface and is ground in the form of an exact radius. A small pin near the back end fits in a groove which has an opposing spiral surface and retains the tool in close contact with the other cam surface to insure correct contact at all times as well as to withdraw the tools to the starting position as soon as the cut is finished.

Tools For Various Purposes

The tools shown at the right hand side of this illustration are for producing internal splines. Three of the tools shown represent types for cutting teeth and the two shown at the extreme right are types used for removing burrs raised by the other tools in certain classes of work. Two gang tools are shown, one for cutting saw teeth and another for cutting gear teeth. The use of gang tools is a great advantage in many cases particularly when cutting gears or other products having a large number of rather small teeth. Another type shown, which consists of an inserted bit set in a holder is somewhat more economical than the solid type of tool on account of the fact that the holders last indefinitely and the cost of replacing the small inserted bits as they become worn is comparatively small. The second and fourth tools from the left are roughing tools which are used in connection with the forming or finishing tools adjacent to them in the photograph. When used in the machine, the roughing and finishing tools are set alternately about the gear blank, the roughing tools slightly in advance of the finishing tools. As the gear is indexed and the tools are fed in gradually, the roughing tools cut grooves the width of the bottom of the tooth space and the finishing tools cut on the sides only, thereby eliminating the crowding and interference of the chips and consequently prolonging the life of the cutting edge of the finishing tools.

Cutting Head Cams

The individual cam lugs are mounted on a large ring which surrounds the tool bits and spacing plate and are held down by T bolts which fit in a circular T slot in the ring. The tool bits are adjusted individually along the T slot relative to the cam ring and each other. Rotary feeding movements are imparted to the cam ring through a gear train seen at the left side of the tool head in Fig. 2, and are produced by a feed mechanism located on the left side of the machine as seen in Fig. 2. The final depth to which the tools are fed is determined by an adjustable micrometer stop located on the front side of the tool head, which positively limits the rotary feeding movements of the cam ring. The feed mechanism being spring actuated, the position of the depth controlling stop can be varied within reasonable limits without re-setting of the feed mechanism. This is particularly desirable during the operation of the machine in cases where the tool bits may not have been set to exactly the right depth in the beginning or in cases where the keen wire edge wears off the tools and begins to cut gears that are uneven or oversize long before they are actually dull.

Accurate Adjustment

The micrometer stop which controls this adjustment, being located at the tool head in a very convenient position, can be re-set by the operator within less than one minute of time even while the machine is in operation. In order to provide relief to prevent the tools from dragging during the back stroke of the ram, a reverse feeding movement is imparted to the cam ring, and before the beginning of the cutting stroke, the forward feeding movement of the cam is made great enough to compensate for the slight retraction for the relief and also to provide the necessary additional feed for the depth of the next cut. The large cover plate on the top of the tool head is used to intermittently clamp and release the tool bits during the cutting operation. The tools are clamped during the cutting stroke and unclamped at the end of the cut so that they may be relieved and fed forward again and then reclamped ready for the next cut. This clamping movement is accomplished by means of an eccentric which is oscillated by a cam on the main crank shaft of the machine. This clamping movement by forcing the V shaped seat of the tool bit into the corresponding V shaped seat in the spacing plate in the tool head serves to centralize and accurately locate the cutting point of the tool and, in addition, to take up all clearance and looseness so as to eliminate vibration and chatter.

Feeding Mechanism

The feed mechanism shown in Fig. 5 and Fig. 2 consists of the cams and levers for producing the feeding and relief movements just described. The spiral cam seen near the centre of Fig. 5 is rotated slowly and intermittently by means of a ratchet through a worm and wheel connection. The rotary movements of this cam gradually force the fulcrum stud of the feed arm forward which, in turn, produces a longitudinal movement of a sort of rack slide which is connected by a gear train to the feed cam gear on the tool head. This feed rack is made in the form of a worm which engages a worm wheel so that adjustments may be made by rotating the worm, thus advancing or withdrawing the position of the tool bits without necessitating any change in the longitudinal position of the feed rack itself.

Return Stroke Relief

The relief movement of the tools is derived from a cam located on the crank shaft and a rocker arm seen at the left of Fig. 5 and is transmitted by a connecting rod to a stud at the upper end of the feed rocker arm. The relief cam rocker arm is provided with a T slotted extension which actuates the feed ratchet through a bevel gear segment and pinion. By adjusting the feed connecting rod stud along the T slot in the rocker arm, any desired fineness or coarseness of feeding movement may be obtained. A strong spring is attached to the relief rocker arm to hold the follower roller in contact with the relief cam on the crank shaft. A somewhat weaker spring is attached to the feed rack slide for holding the fulcrum stud roller of the feed rocker arm in contact with the spiral feed cam. By varying the shape of the feed cam, any sort of

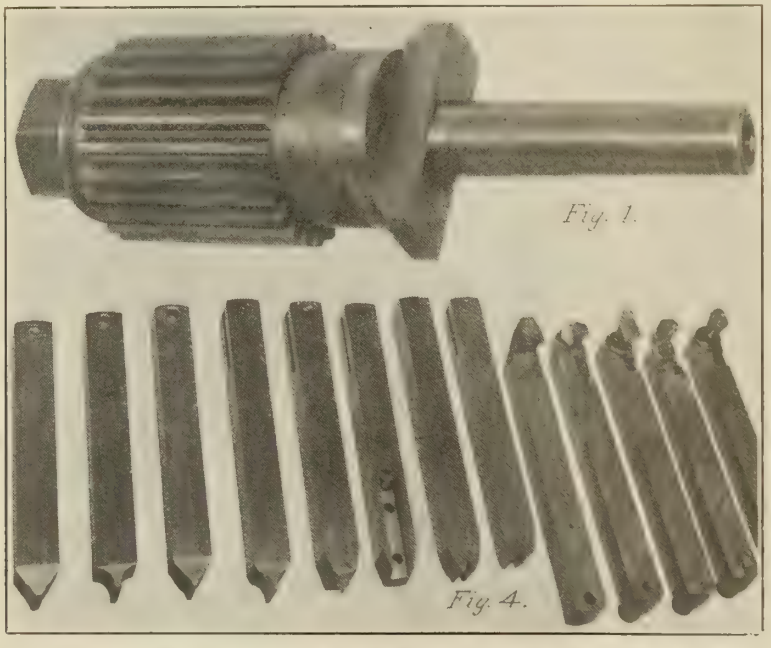

Fig. 1—Interchangeable arbor with six gears. Fig. 4—Group of cutters used for various purposes.

feeding movement can be secured. It can be seen from the illustration, that this cam has a long gradual slope for the feeding movement and a sharp descent for quickly returning the tools to their starting position at the completion of the cutting operation.

The cam also has a cylindrical dwell portion at the end of the spiral feed section and before the returning slope. The purpose of this dwell is to hold the tools in at the full depth position for a sufficient number of strokes to permit the gear blanks to be indexed one complete revolution in order to permit some one tool to take a last finishing cut on all of the teeth.

Indexing the Work

The indexing mechanism as shown in detail in Fig. 6 consists of two semi-cylindrical guides, one of which is attached to the ram spindle, the other being attached to a revolving drum on which is mounted a large spur gear driven through change gears by a pair of intermittent Geneva gears, encased in an oil-tight housing, and which, in turn, are driven from the crank shaft by means of a long connecting shaft seen in Fig. 5. The intermittent shaft driven gear and the compound gear shaft driven gear are used as change gears and by varying their ratio any desired number of divisions may be indexed. The compound gear shaft centre distance is adjustable with reference to the large index gear and also the intermittent shaft gear so that practically all back lash may be taken up. A differential washer is incorporated as a driving member between the intermittent shaft and its gear to provide an angular adjustment for cutting gears which have keyways, etc., which must have an exact location with respect to certain gear teeth.

Interchangeable Arbors

The work arbors used in this machine, as shown in Fig. 1, are interchangeable and are provided with a tapered shank and a thrust collar made in the form of a large face key. The tapered shank fits the tapered socket in the ram spindle and the thrust collar fits a corresponding keyway in the spindle and provides an accurate angular location for the arbor and also prevents the taper being thrust too tightly into the socket. The gear blanks are put on the arbor and fastened in place by a nut while the arbor is held in a vise-like fixture attached to a bench at the side of the machine.

The mechanism for driving the ram and producing the reciprocating motion for cutting purposes and the temporary elevating and lowering motion for changing work arbors consists of a crank that drives a reciprocating rack slide, which, in turn, transmits its reciprocating motion to the ram through two gears mounted on a rock shaft. This rack slide is made in the form of a worm and engages one of the gears on the rock shaft which is made in the form of a worm wheel. During the reciprocation, which produces the cutting motion, it operates in the same manner as a reciprocating rack.

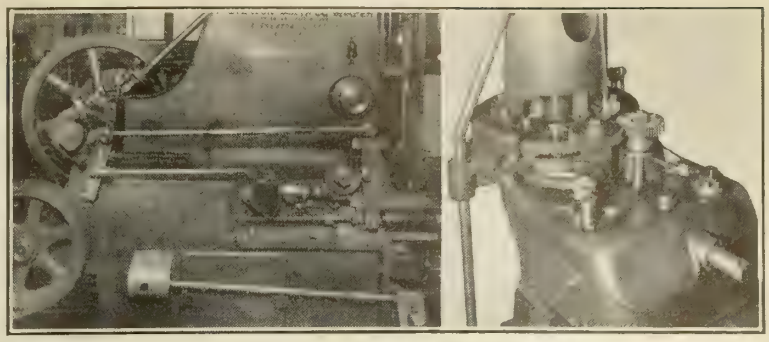

Fig. 5.—Left: view of feed mechanism. Fig. 6—Right: indexing mechanism located at top of machine.

Elevating the Ram

When it is desired to produce the temporary elevating of the ram for changing arbors, the rack slide is held stationary from reciprocating and is given a rotary movement the same as a worm, which rotates the worm wheel and rock shaft and in turn elevates or lowers the ram. This rotary movement is obtained through a gear train and is derived from a small motor which also furnishes power for actuating the drawbolt mentioned before. The amplitude of the elevating and lowering motion of the ram is controlled by adjustable stop collars placed on the shifting rod which engages and dis-engages the driving clutches. The crank head is slotted and the crank pin is made in the form of a T bolt and may be adjusted to provide any length of stroke from zero up to six and one-quarter inches.

Graduations are provided on the crank head for indicating the length of the cutting stroke. These graduations are made of the proper length to compensate for the extra length of stroke needed to provide the necessary over-travel before and after the cut begins for indexing, feeding, etc. Thus the operator merely measures the face width of the parts being cut and sets the stroke according to the corresponding graduations and knows that the proper over-travel is automatically provided.

Setting for Position

In order to set the ram and work in proper relative vertical position to the tools, a stationary pointer is attached to the machine frame and a corresponding mark is placed on the crank head in such an angular position with reference to the crank pin, so that when the mark on the crank head is set opposite the pointer, the ram may be adjusted downward until the lower side of the blanks is even with the cutting edge of the tools. The elevating control stops are then set to correspond to this position and require no further attention from the operator. This feature has been found to be a great convenience to the operator and to practically eliminate mistakes in this part of a set-up.

The following is a record of some of the work performed on these multiple shaping machines:—

Gear.—10 P, 24 T, ½in. face, 12 cutting tools, 50 strokes per min., 6 blanks on arbor, cutting time 2.4 min., cutting time per gear .4 min.

Sprocket.—3 in. dia., ⅝ in. p., 12 teeth, 12 cutters, 50 s.p.m., 16 blanks on arbor, total cutting time 3.7 min., time per piece, .23 min.

Shaft.—1½ in. dia., 6 splines, 50 s.p.m., time per shaft 1.35 min.

Reamer.—1 in. machine, 8 flutes, 50 s.p.m., time per reamer 1.04 min.

Cutter.—3 in. milling, 12 teeth, 50 s.p.m., 8 blanks on arbor, total time 2.9 min., time per cutter .36 min.

Saw.—Screw slotting 2¾ in. dia., 72 teeth, 36 cutting tools, 50 s.p.m., 120 on arbor, total time 1.3 min., time per saw .01 min.

EIGHT-HOUR DAY ADVANTAGES

REPORTING on "Work Periods in Continuous Industry," a committee of the Federated American Engineering Societies states that there are few continuous industries which do not have some twelve-hour plants; but of some forty or fifty continuous industries a number are operating almost entirely on three shifts, while the majority are partly on two shifts and partly on three shifts, with three-shift operation in the preponderance. The investigator of the steel industry was assured by blast furnace operators on more than one occasion that the cost of producing pig iron was less on the eight-hour than on the twelve-hour day. Outside the steel industry the total number of employees on eight-hour shift is now considerably larger than the total number of employees on twelve-hour shifts. Taking into consideration all continuous industries, between one-half and two-thirds of all workers on continuous operation are on shifts averaging twelve hours.

In a number of plants where the change has been made with success the management reports these results:

Better physical and mental condition of workmen.

Improvement in class of workmen.

Less shirking, tardiness, absenteeism

Figuring Costs from Material to Product - No.1

Opening General Ledger Accounts—Material, Labor and Indirect Expense—Beginning at Foundry in Estimating for Machinery Plant—Accounting for Every Detail

By A. LUENBERG

KNOW WHAT IT COSTS

This is the first of a series of articles on cost-accounting as having practical application in machine tool production. Questions, discussions or suggestions upon the different phases of the subject are welcomed.

INTERNATIONAL reconstruction and the business depression in Canada for the last two years have forced many Canadian manufacturers to look for export trade, and enter upon international competition. A comparatively small number of manufacturers know the cost to manufacture and sell, and unless that fact is known, success on the world market may be considered very doubtful.

No business man, no matter how small the business may be, should be without some kind of cost system. At the present time where nearly every manufacturer has to figure on large competition it is absolutely necessary to know accurate factory cost. Accurate knowledge of factory cost is the foundation to success, where ignorance may be the direct cause of failure sooner or later.

The installation of a cost system makes it at once necessary to open general ledger accounts for what makes up factory cost—material, labor, and indirect expense. To get a start, an inventory must be taken of all materials on hand at a certain time. Materials may consist of raw materials, parts in process of making or parts finished and ready for shipment. A separate account should be opened for each class and named something like the following, for a company manufacturing machinery:

1. Raw Material & Supplies.
2. Foundry Raw Materials & Supplies.
3. Foundry—Work in Process.
4. Machine Shop—Work in Process.
5. Erecting—Work in Process.
6. Finished Parts.
7. Rough Casting Stores.
8. Payroll Account.
9. Indirect Expense.
10. Completed Machines

Every account must be debited and credited at proper times, say monthly periods, as raw materials are received or work is proceeding in plant. The following description will deal with how to find accurate factory costs of rough-castings. The system is in operation at one of the largest Canadian manufacturing concerns in the line of machinery, making their own castings.

How To Find Cost of Rough Castings

(See "Foundry Cost of Production" report.) In order to get the actual cost of rough castings, it is necessary to know the exact cost of foundry raw materials at the plant. In charging the cupola, all pig iron, scrap iron, steel, coke, limestone, etc, must be weighed and a record of same kept by person responsible for heat report. Nothing must be overlooked, no matter how trifling; everything must be charged at its proper value. The total weight of materials entering the cupola at their cost price at the plant represent the cost price of raw material per heat. Wages of cupola help, direct and indirect, as well as the department's fixed overhead charges, are then added to the cost of raw material. The result, divided by tonnage, gives what is called the price per pound at the spout.

The fixed overhead charge of a department is a proper share of general overhead expenses fixed for a certain department according to its size, its use of power, light and heat, its proper share of repair costs, maintenance and general administrative expenses, depreciation and in many cases, selling expenses.

The next step is to include core-room expenses into cost. All core oils, core sand, core compound, coke, etc, used in connection with core-making for a heat must be kept track of, and charged against the heat, adding coremakers' and core-room helpers' wages as well as the department's fixed overhead charges.

Knowing cost of heat at spout and core-room expenses the moulding shop must be taken into account. The total of cost of heat at spout plus core-room expenses as explained above minus foundry returns (drop-shot-grates and sprues) at scrap iron cost prices, are the figures to work from.

Moulders' and moulding shop helpers' wages, supplies used and the department's overhead are added. The result divided by tonnage will give the price per pound of castings in mould.

To arrive at the final cost of rough castings, the chipping and cleaning department must be included. Chippers' and chipping room laborers' wages and the fixed department's overhead are added to cost of heat in mould. The foundry bad castings are deducted at scrap iron value giving the accurate cost of heat. Tonnage divided into cost of heat is price per pound of good castings produced by foundry.

In order to get accurate figures for all productive and indirect labor, it is best to employ a man to check the actual number of men, productive and indirect, working on a heat, and figure out their wages at rates paid. The same employee will have time enough to take care of heat reports, make out requisitions for foundry materials used by all departments, checking patterns and keeping a record of castings for each heat. The record of castings per heat is very important, checker must go to every moulder and find out pattern numbers and number of pieces in mould. In a foundry where a heat is taken off daily, the chipping department may not

Finishing Crankshafts in the Grinding Machine

High Degree of Accuracy and Finish Attained—Special Facilities to Prevent Stresses in Shaft—Special Throw Blocks and Steady Rests—Locating the Grinding Wheel

By R. E. W. HARRISON, A.M.I.A.E.

FINISHING, and in some cases the roughing and finishing of single and multi-throw crankshafts on the precision grinding machine is now generally accepted as being one of the most economical means whereby both accuracy and finish may be attained. In this, as in all other branches of the art of grinding, rapid progress has been made during the last few years, and it is the intention to set out here a few of the more important details which have matured.

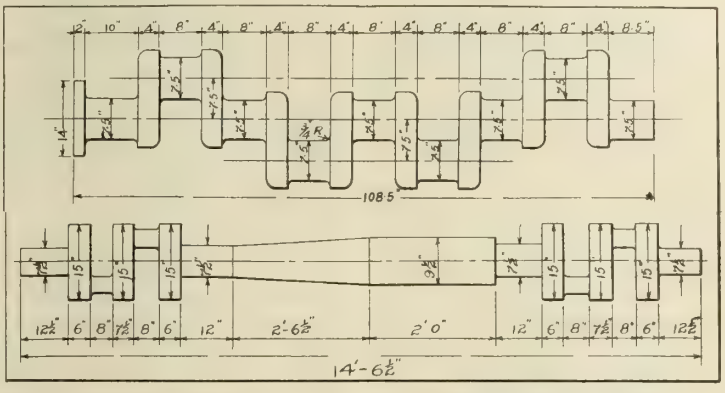
Securing Shaft Alignment

The finishing of crankshaft pins and bearings, both for single and multiple throw crankshafts, is a class of work peculiarly applicable to the grinding machine, owing to the high degree of accuracy and finish demanded. One of the difficulties encountered in any method of machining crankshafts is the securing of alignment of the crank pins in relation to each other, owing to the gradual release of the various stresses in the shaft forgings while the machining is proceeding step by step. It is for this reason that the grinding machine has been so successful on this class of work, the removal of the surplus material by grinding being a more gradual operation, and one that does not impart further stresses to the shaft. Crankshafts can also be economically ground direct from forgings or stampings, but if the full benefits of this method are to be obtained, the forgings must be specially designed to give the necessary clearance for the sides of the wheel.

Full Width Wheel

The method adopted in the grinding of crankshafts is the use of a grinding wheel equal to the full width of a crank pin or bearing, using the wheel in much the same manner as a broad forming tool in the lathe, no traverse of the crankshaft being necessary. The fillets on the shaft are formed direct by the wheel, a special device being fitted to the machine for forming the corners of the wheel to the correct radii. The necessary support to the shaft whilst grinding is given by a specially designed steady, which supports the shaft against the thrust of the wheel. For this work plain grinding machines are used with the addition of crankshaft equipment, and specially arranged to carry the large diameter grinding wheels necessary for grinding crank pins.

Author is assistant works manager of the Churchill Machine Tool Co., Broadheath, Manchester.

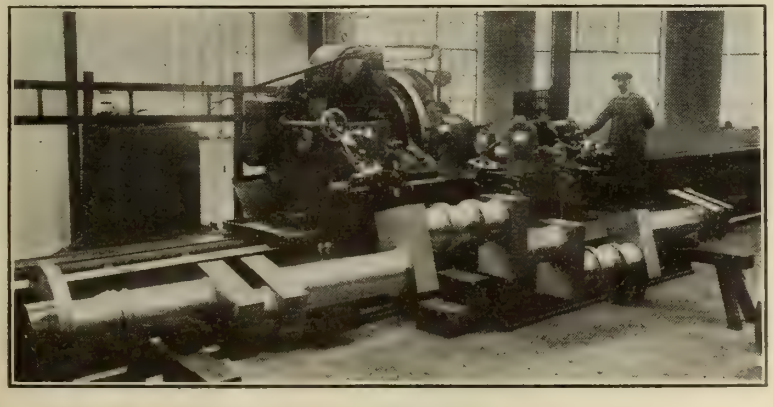


Upper—Crankshaft finished on 50 in. x 300 in. plain grinder, removing .125 in. or pins and .04 in. to .05 in. on bearings; limit, .00075 in. for round and .00025 in. for size and parallel; sides of web are ground to width gauge. Time —3¼ hrs. for pins, 3 hrs. for bearings. Lower—Crankshaft finished on 36 in. x 192 in. plain grinding self-contained drive. Finish ground where dimensioned removing .030 to .045 in. of stock, in 2¾ hours.

General Equipment

The equipment generally consists of: Adjustable throw blocks, setting gauge, special steadies, radius truing device and locating device. Lengthy experience has proved that the old type of throw block used for grinding the crank pins was inefficient inasmuch as the shaft being ground was kept under varying degrees of compression even during the final operation resulting in the production of work which could not be accepted under the standards of accuracy demanded in present day practice. This disability was due to the design of the throw block —an undesirable feature which has been entirely removed with the present improved design.

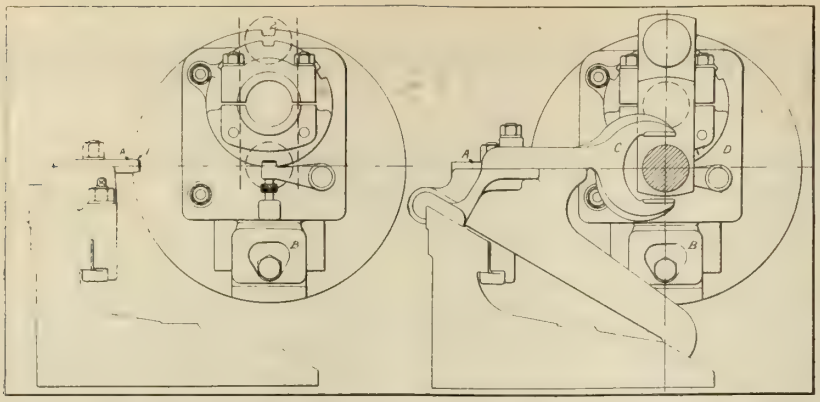
With the new type of throw blocks supplied with crankshaft grinding machines today, the crankshaft is supported in bearings, so that it is in no way subjected to end thrust, in fact, it is possible, if desired, to put the shaft being ground in tension. These new throw blocks are adjustable for stroke, so that one pair will cover all the sizes of the crankshafts that the machine will swing. Distance pieces are provided, machined to the throw dimension for governing the length of the crankshaft stroke. These distance pieces are plain metal blocks, easily attached or changed for different stroke.



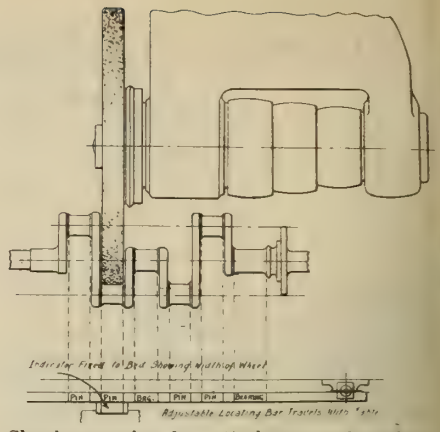
Finish grinding on large crankshaft.

Throw Block Bearings

The bearings in the throw blocks are accurately divided for three, four or six throw crankshafts with full provision for securing the pins in accurate alignment. Each throw block is mounted on ball bearings, and thereby torsional stresses in the crankshaft are reduced to a minimum while grinding is proceeding, a feature which has an important bearing on the accuracy and alignment of the finished crankshaft. The benefits secured by the design of throw blocks shown are, ease of manipulation and interchangeability of product due to



Showing first position of throw blocks when inserting crankshaft in machine. Spacing block B, which equals throw of crank determines length of stroke. Cap in setting gauge C in central with machine centres and will indicate any error in pin position.



Showing spacing bar attachment and setting.

the elimination of bending caused by end pressure and the removal of all torsional stresses due to friction.

Locating and Setting

The setting gauge is a device introduced and supplied to enable the operator to set the crankshaft in its correct grinding position without difficulty and in a minimum of time, and by its use, crank pins can be quickly and definitely located.

The locating device governs the position of the various pins and journal bearings of the crank. It is in the form of a graduated steel bar, adjustable lengthwise on the table, the graduations indicating the position of the pins and journals. Fixed to the bed of the machine is a gauge corresponding to the width of the grinding wheel, so that when the crankshaft is inserted in the machine the adjustable graduated bar is moved to correspond with the wheel width gauge when grinding the first bearing. The other bearings are then ground in accordance with the graduations on the bar.

The steadies used for supporting the crank pins when being ground are smaller in capacity than the steadies supplied for ordinary plain grinding, and also much narrower to allow of the rests passing between the webs of the crank. The tops of these steadies are each arranged to carry the radius truing device.

The radius truing device is used for rounding the corners of the grinding wheel to the radii of the fillets. It can be attached to the top of one of the steadies and used without removing the work from the machine.

Method of Procedure

The sequence of operations when grinding a crankshaft is as follows: (1) Rough grind to within .030 in. - .035 in. of finish size all journal diameters. (2) Rough grind pins to within .100 in. - .125 in. (3) Finish pins. (4) Finish journals. One of the most important factors contributing to the rapid production attainable with this design of throw block is the facility with which the surplus metal on the pin diameters may be ground away. This factor then makes it possible to allow a greater margin for the finishing operations than would otherwise permissible.

It will therefore be appreciated that there will be a considerable saving in time affected by the operator when, in the final operation on the pins, he is armed with the knowledge that he has a comparatively large surplus of metal available, which fact means that he is not compelled to check and re-check the alignment of the pins as frequently as would be the case if there were barely sufficient margin left on the pins to ensure cleaning up to size. Whatever commercial degree of accuracy may be demanded from the whole of the machining operation, the alignment of the finished journals must be above reproach, and it is by grinding these portions last on dead centres that this result is most easily obtained.

With careful operation the machine will produce crankshafts to any desired degree of accuracy and with a finish direct from the wheel which calls for neither a lapping nor a polishing operation of any description whatsoever. These results being obtainable with production maintained on a commercial basis.

The rough and finish grinding of crankshaft journals is a straight-forward plain grinding operation, but care should be taken to ensure that the tailstock centre does not exert an excessive end pressure, and that the work stays are used and so disposed that they take the thrust of the wheel without permitting any deflection in the work. In pin grinding the operation makes a somewhat heavier demand on the skill of the operator, and calls for special care in the setting up and manipulation of the work stays.

The sequence of operations also is dependent on the state of the crankshaft when it comes to the grinding machine, for instance where the pin is to be ground from the rough forging, a rough grinding operation is necessary, this is also the case where the shaft is rough turned first owing to the release of forging stresses during turning, and as a result a large amount of metal has had to be left on. The sequence of operations is as follows:—(a) Set cradles to correct throw using spacing blocks provided. (b) Place in position in cradles, bushes of the correct diameter to suit the shaft being operated on. (C) With locating bolts A in slots 1 place crankshaft in cradles and set with centre

?? Questions and Answers ??

HEATING WITH OIL

Question:—Is it possible to heat efficiently with oil a three-storey manufacturing building, 100 feet square, by using an ordinary furnace situated on the ground floor? We hear that it has been done.

Answer:—Heating buildings by means of an ordinary stove on the ground floor is by no means unusual, and the choice of fuel is governed by local conditions. If oil fuel is used, it must be fed through a special burner, and atomized either by pressure or gravity head. We would not think there should be any difficulty in burning oil this way. The relative heat value of oil to coal is about 1½, that is one pound of oil has 18,000 B. t. u. to an average of 12,000 B. t. u. of coal. Notwithstanding this advantage, the relative price may be such as to exclude oil. Wood has a heat value of about 8,000 B. t. u. per lb. We know of a case where such a building was heated by means of an ordinary hot air furnace. The firebox contained firebrick which was heated by a flame from an ordinary oil burner inserted underneath. The oil feed was by means of a very small electrically-operated pump. The furnace was pipeless and, apart from the stairway, no special floor openings had been made to permit of air passage. There is no specific data on the matter but the owner of the building declared that the apparatus served his purpose and was economical.

PRICES ON MUNICIPAL CASTINGS

Question:—We have a foundry and machine shop and would like to know what is considered a fair price for municipal castings under present conditions. There seems to be a great difference of opinion on this matter and keen competition is probably responsible for much work being done at starvation prices. Gate valves are also sold by the piece, 2-inch valves being quoted at $4.10 while the 6-inch are quoted at $16.50. These prices, which are a fair average of what were contracted for last spring, would yield a good profit under present conditions although none too high. It is a simple matter for a good foundryman to figure exactly what it costs to produce his castings, and then the speculation is what competitors will want in way of profit. Machining may be included in the price or may be considered as extras. As a rule very little is required.

Answer:—Municipal castings are being specialized on the same as everything else, and the foundryman who is equipped for producing them can make money at prices which would mean a loss to those who are not. Prices are, of course, cut closely and ordinary gray iron castings such as gully grates and sewer manhole castings range between $2.90 and $3 00. Water mains, which cannot be made in anything but pipe foundries, were quoted in the spring at $62 per ton, and contracts were taken for the year at this price, while the cast fittings brought 5 cents per pound. Extension boxes are sold by the piece, from $2 to $3, according to size.

Canadian Machinery and Manufacturing News would have its readers feel that its resources for gathering special information, such as they may require, are freely at their service. Their questions will receive immediate consideration. On the other hand, should they feel that they are in a position to add to the information given in these columns upon any subject, their co-operation will be greatly appreciated. Desired information is first sent by mail to enquirers. Names will be supplied upon request.

LEAKAGE OR EXPLOSION

Question:—In any insurance policy covering our boiler plant and steam piping we are covered, I understand, for explosion, rupture or collapse of any part of the system. There is a clause excluding leakage at joint. A gasket falls between two flanges in the ordinary course of events. In the event of damage, to what extent, if at all, may we claim under this policy?

Answer.—This is a point depending, to a certain extent, upon circumstances and the interpretation of the terms "leakage" and "explosion." A case of much interest to manufacturers and other owners of boilers and pressure apparatus who cover this apparatus with insurance, and to the issuers of such policies was tried in the High Court recently. This was an action on the part of a policy holder to recover damages on a policy covering the pressure piping on an ammonia refrigerating machine, but exclusive of the compressor itself. The policy was of the usual type, that is, it covered any damage arising directly from the rupture or collapse of any of the pressure piping, but expressly excluded any leakage at joints or couplings. The plaintiffs were the Toronto Packing Co., and the defendants the Royal Indemnity Assurance Co. The action arose out of an accident at the plant of the plaintiffs. The refrigerating machine is driven by a belt from a motor, and on the morning of the accident, the machine was started up in the usual way, but it is alleged, that the operator forgot to open the valve between the compressor and the condenser, with the result that after a short period, the rubber gasket in between two flanges was blown out by the pressure. The plaintiffs claimed that this was an explosion in the meaning of the policy, and claimed for the damage due. A room full of meat had been spoiled by the fumes of the escaping ammonia. The insurance company, on the other hand, claimed that this was a leakage at a joint, and as such expressly exempt under the clause of their policy dealing with this condition. Experts were called by both sides to define just what was the difference between an explosion and a leak, but the learned judge would not admit evidence of this kind, taking the ground that the word rupture or collapse in the policy rendered the insurer liable for damage. He held that a rubber gasket between two pipe flanges was essentially a part of the pipe, and could not be considered anything else. The damage then in his opinion was due to the rupture or collapse of the gasket, and as such constituted an explosion. Damages were accordingly awarded to the plaintiff as well as the costs in the action. The case may be appealed.

This department would welcome further discussion of this question.

ACCOUNTING SYSTEM WANTED

Question:—We wish to revise our cost system. Have you any suggestions that may be helpful to us? In our foundry and machine shop we employ 60 to 75 hands.

Answer:—With the present number of Canadian Machinery, we are featuring the first of a series of articles on cost accounting by an experienced accountant in the machinery business. The series will deal with different departments in order of their proper relation to the business as a whole.

* * * *

Good judgment in the selection of equipment and a reasonable amount of proper attention to such tools after they have been placed into service should enable the small shop to take care of many jobs of accurate tool and jig work provided a capable man is in charge of the shop. Initiative is the most essential factor in making a paying proposition out of a small machine shop where the staff is called upon to perform a wide variety of work at irregular intervals.

Heat Treatment of Steel in Crucible Furnaces

Uniform Heat of First Importance—Pressed Steel Pots Give Good Service—Avoid Overheating of the Work—Handling Parts in Quantities—Preventing Formation of Scale

APPLICATION of the crucible furnace for the heat treatment of steel is not an innovation, as old time steel masters knew of it and practised it with varying results, depending on their knowledge and ability to determine the temperature of the bath. In those days pyrometers were either unknown or unreliable, and Seger cones were relied upon for accurate results. The craftsmen of our fathers' days were trained to judge temperatures by color, and crucible furnaces using a molten bath did not readily lend themselves to this old method of judging temperatures, and the Seger cone could not be used. The top of the bath was generally covered with dross, or a slight film of oxide, thus making temperature judging rather difficult and generally too high. This characteristic of crucible furnaces resulted in the production of overheated work and the process fell into disrepute, even though conceded to be an excellent method for heat treating.

A careful study of this type of furnace was made in later years, and with the development of the pyrometer to where it could be relied upon implicity, crucible furnaces have come into their own, and are specified by many manufacturers for use in the production of exceptionally fine heat treated work.

Furnace Construction

Crucible furnace construction for heat treating purposes require to be especially designed to obtain maximum efficiency. It is not simply the placing of a pot within a setting of brick and applying heat to it. Uniformity of heat is the prime object of the process, and this can be obtained only after careful design and experimentation. The action of the flame is also important, as it should not strike directly on the pot, for this will shorten the life of the pot considerably. The design that has given great satisfaction is the circular type which permits the placing of the burners so that direct impingement of the flame on the pot is prevented and a swirling motion is given to the flame, causing it to encircle the crucible several times before passing out of the flue. This holds true for either gas or oil fired furnaces. Less economy is shown with rectangular furnaces, owing to the short contact and high velocity of the gases in the combustion chamber. In crucible furnaces pressed steel pots give greater satisfaction than either cast iron or cast steel, due to the greater ductility and higher relative heat conductivity of their thinner walls. The life of any pot is materially increased by proper regulation of the atmosphere within the combustion chamber. A reducing or soft flame is best.

Methods of Heating

In an oven furnace the heat is transferred by convection and radiation, as the furnace is so designed that the flame will not come in direct contact with the work. In the crucible furnace the heat is transferred by conduction, which is many times greater than any of the modes available in the oven furnace.

This is demonstrated by the example of one being able to hold the hand several inches away from a red hot object for quite awhile, the heat being transmitted by radiation and convection, but knowing better than to touch the red hot object for fear of being severely burned, the heat being here transmitted by conduction. So great is the difference between the two types that an illustration or demonstration is needed to convince the uninitiated before they will believe that a crucible furnace using molten lead will heat the work up about 70 times faster than an oven furnace. It takes about 12 seconds to heat a piece of 3/16 inch steel in a lead furnace at 1450 deg. F., while at least 15 minutes is required in an oven furnace maintained at 1450 deg. F. Since the crucible furnace heats the work up so rapidly, it is imperative to preheat all work of uneven cross section.

Uniformity of Heat

Rapid heating is not the only advantage crucible furnaces have over other systems of heating steel. They heat uniformly, and this uniformity of temperature is throughout the entire crucible of molten salts or metal, and is a positive guarantee that the pyrometer indicates the exact temperature of the work. Non-uniformity in heating necessarily results in non-uniformity in cooling, which is the cause of most of the warping and cracking in the hardening process, and hardening cracks are more often the result of uneven heating than defects in the steel, both of which are not inherent in the crucible heating process.

One of the greatest weaknesses in heat treating practice is that of overheating of the work. Both workmen and charge hands are frequently responsible in this respect. In crucible furnaces this excuse is not to be tolerated, as the workman cannot see the work all the time, and it heats too rapidly for him to withdraw it at the "right time." The removal of this one bane of the heat-treating room is sufficient to recommend the crucible type furnace, for it is an axiom of the heat treater that best results are obtained by hardening a piece of steel at the lowest possible temperature, and always on a rising temperature, never a falling one. The most important function of the crucible furnace, other than its delivery of rapid, uniform heat, lies in its production of work without any decarbonized surface or scale; in fact, when cyanide is used, carbon is actually added to the surface layer of the steel.

Universal Application

Crucible furnaces may be adapted to any requirements of the heat treating field, dependent entirely upon the man or organization. In the beginning they were used for heating only very small parts, where uniformity of "temper" was required, but larger furnaces have since been produced for handling large parts wherein uniformity of hardness is essential at minimum expense.

Crucible furnaces lend themselves admirably to heat treating carbon steels, and similar low temperature alloys hardening below 1600 deg. F., using lead or some of the compounds in the market as the heating medium. For high speed steel barium chloride was formerly used exclusively, in spite of its shortcomings, but today this salt has been displaced to a great extent by other compounds. For hardening of high speed steel, however, the crucible furnace has fallen into disuse within recent years, being replaced by the oven type furnace and double deck furnace (see illustration), due principally to the fact that high speed steel parts are generally not very numerous.

The use of the crucible furnace for tempering at any temperature below 1,200 deg. F., is quite common. For lower temperatures the oil tempering furnace is used, as shown in illustration. This furnace when a high flash point oil is used will operate as high as 650 deg. F. nicely, after which a furnace of the rectangular crucible type, like illustration, must be used with an alloy of lead and tin as the heating medium. Using the crucible furnace for tempering overcomes the many weaknesses of the color tempering process, removing the personal element and cutting down labor costs to a negligible figure, as thousands of parts can be tempered at a time.

Carbon steel is the most generally used grade and where this steel is to be hardened lead works very satisfactorily. Here are a few suggestions in

As recommended by the American Gear Manufacturers' Association.

using lead: It is very necessary to place a hood over the furnace to carry off any lead fumes which may arise from the pot. Charcoal or old carburizer may be used to cover the surface of the lead to prevent oxidation and lessen the sticking of the lead to the work. Slag should not be thrown away, as it can be reduced back to the metal while red hot on top of the pot by means of charcoal.

It is common knowledge that when a piece of steel is heated in an oven furnace in which an oxidizing atmosphere is maintained, its surface is decarbonized for quite a depth. This cannot happen in a lead pot, and for this reason the lead pot furnace continues to be, as for years, the one furnace in which files can be successfully hardened.

Many baths and compounds are on the market, any of which should be satisfactory, providing their melting points are correctly chosen for the temperature at which they are to operate. For example: If a drawing temperature of 720 deg. F., is desired, a temperature too high for oil and a trifle too low for lead (M. P. 621 deg. F.), as it would freeze all over the parts and be slow work, some tin could be added to lower the melting point to 450 deg. F., or a mixture of potassium nitrate 2 parts, sodium nitrate 3 parts, melting at 450 deg., F., could be used.

A table of the salts commonly used to compound these baths follows:

Salt	Melting Point °F.
Barium Chloride	1580
Sodium Chloride	1418
Potassium Chloride	1346
Calcium Chloride	1328
Magnesium Chloride	1306
Lead Chloride	932
Cupric Chloride	928
Ferric Chloride	572
Zinc Chloride	504
Aluminum Chloride	356
Potassium Carbonate	1526
Sodium Carbonate	1317
Lithium Carbonate	1283
Potassium Nitrate	644
Codium Nitrate	572
Calcium Fluoride	1832
Magnesium Fluoride	1664

Of the above salts calcium chloride combined with sodium chloride and admixtures of sodium carbonate are most generally used.

One of the most common baths is lead of commercial purity, which melts at 621 deg. F., and may be used up to 1,600 deg. F., satisfactorily. In order to prevent the adherence of the lead to the work it may be dipped into a solution made up of 1 pound potassium cyanide dissolved in 1 gallon hot water, and thoroughly dried.

Summary

1. Crucible furnaces for heat treating have been in use after a fashion for many years, their revival and widespread use to-day being occasioned by the perfection of the pyrometer, whereby the temperature may be controlled.

2. The construction of a crucible furnace is the result of considerable experimental work, the circular type being found most satisfactory.

3. Comparative merits of the oven type furnace when compared with the crucible type show the crucible furnace to heat the work at least 70 times faster without scale, decarburization or non-uniformity, which tends to produce better work.

4. High speed steel and carbon steel hardening and tempering are all done in crucible furnaces very satisfactorily. High speed steel hardening in barium chloride is being abandoned in favor of the double-deck oven type furnace, due to the preheating feature. Carbon steel, readily hardened in lead or any of the numerous salts, compounds or cyanided, is being carried out more than ever in the crucible furnace, because of its many desirable features. Oil or low temperature tempering is commonly done in a crucible furnace.

5. The use of lead as the heating medium for carbon steels is common practice.

6. Many salts for heating mediums are on the market, all of which are compounded from a certain series of salts, a table of which is given.

The use of the crucible furnace is now established as one of the most accurate and satisfactory methods of heat treating small parts in quantity, where scale or decarburizing cannot be tolerated or where an increase in the carbon on the surface is desired by cyaniding. The process is productive of accurate work, uniformly heated, even when unskilled labor is used.

FIGURING COSTS FROM MATERIAL TO PRODUCT NO. 1

(Continued from page 16)

be able to get castings of one heat cleaned up every day. By checking castings leaving foundry against castings on heat lists, the employee making out the heat reports, will be able to find out just when the last casting of a previous heat has left the foundry and enable him to finish report for that heat. This record of castings per heat must also show the number of hours moulder put in on a certain number of castings. The foundry foreman should look over this record and find out if time put in on jobs is O. K., and if not he can at once go after offending party and in such a way help to keep down foundry cost of production.

For all raw materials and supplies used in connection with heats for a certain period:

FINISHING ENGINE CRANK SHAFT

(Continued from Page 18)

gauge C until the centre line of pins to be ground coincides with the centre line of the machine. (d) Withdraw locating bolts A and insert in slot 2. This revolves the crankshaft through 90 deg. and enables the circular check on the pin diameters to be completed. The pin is then in the correct grinding position. The remaining pins on either 2, 4 or 6 throw crankshafts can then be ground using the dividing plate embodied in each cradle.

General Repair Work

A special machine with a capacity 18 in. swing x 60 in. length between centres has been developed for this class of work, where there is a multiplicity of the types of jobs to be handled. The main feature of the equipment is the addition of a three-jaw chuck mounted on each throw block, these being provided to take care of the widely varying diameters of worn crankshafts which have to be contended with. If bushes were used for each diameter it would be obvious that there would be a tremendous number required.

The left hand chuck or rather the one which is mounted at the driving end, is provided with outside jaws to grip, should occasion arise, on to the flanged end which is a feature of the design of some crankshafts. The other chuck is fitted with inside jaws and both back plates are bored to a suitable diameter to allow the jaws to obtain a grip as close to the pins as practicable.

Heavy Engine Crankshaft Grinding

The illustrations testify to the faith of the builders of the heavier type of engine in the grinding method of finishing their crankshafts. Machines have been made and are now in regular commission on work of this description up to 72 in. swing and taking 23 ft. between centres. Whatever may be the consensus of opinion as to the merits or otherwise of grinding the pins, it is universally acknowledged that exceptionally good results are obtained with shafts which have been ground on the journals, the question of correct alignment being in this case the factor of prime importance and one which is easily assured when once the grinding method has been adopted.

Crankshaft Web Grinding

Refinements with the object of securing better engine running balance have resulted in some instances in the demand for a machine capable of grinding the contours of the crank webs to an accurate predetermined shape and a high degree of finish. This operation is taken care of by fitting a cam grinding attachment to the plain grinding machine with master cams arranged to suit the shape of web desired. The spindle of the attachment being rotated by the grinding machine work head, no further additions as regards overhead works are necessary.

The attachment itself is built on the lines of the standard automobile grinding attachment, and is entirely self-contained.

Standardization of Drills, Reamers and Cutters

Closer Co-operation of Manufacturers Necessary—Production Cost Reduced Through Improved Methods—Too Wide a Range in Small Tool Sizes—Proposed Modification of Standard Practice

By CARL J. OXFORD

MACHINE tools and small tools are so closely related to each other and interdependent that their respective developments logically should go hand in hand. In the past we have had instances of close co-operation between machine tool builders and small tool manufacturers. The results have invariably been noteworthy and beneficial both to the co-operating firms and to the tool-using industries in general.

Powerful and rapidly operating machine tools may be designed and built, but their success is largely nullified if they require cutting tools of prohibitive cost and of short life. Conversely, small tools may be developed which with the proper machine tools will produce wonderful results but which again with unsuitable machines are complete failures.

We have been, and are still, passing through a period in our industrial development where reduction of expenses has become the watchword. Particularly is this true of those expenses which may be classified as production costs. Facing, as we do, keenly competitive markets, it becomes necessary to cut the cost of production to the core, if the manufacturer is to show a balance on the right side of the ledger.

There seems to be but a scant likelihood that either raw material or labor costs will recede to a lower level in the near future. In fact, we have recently seen slight increases in both. The lowering of production costs must therefore be accomplished through improvements in methods, and through increased productivity and efficiency of tools and equipment as compared with first costs.

It is the primary purpose of this paper to point out how greatly the first cost of small tools can be lowered, without sacrificing their efficiency, by the adoption of standards that will permit manufacturers of tools to produce on a quantity basis.

Twist drills, reamers, and milling cutters all are classed as small tools. In this paper only these three types will be considered. Usually the manufacturer classifies them as being either standard or special. Standard tools are those sizes and designs which are regularly catalogued and carried in stock by the larger manufacturers, while special tools are those made up to the customers' specifications.

There exists at present a fair uniformity of general dimensions in the tools catalogued as standard by the various makers. This is a step in the right direction, but the belief is expressed here that this uniformity could be carried more into detail, and that the number of standard items listed could be cut almost in two without any serious handicap to the metal-working industries in general.

It is difficult to realize, by those not actively engaged in the small-tool business, what a wide variety of styles and sizes are catalogued as standard tools. An examination of several tool-manufacturers' catalogs shows the following average number of items:

Twist drills	3,400 items.
Reamers	2,200 items.
Milling cutters	4,500 items.

Roughly this makes a total of 10,000 items. Certainly this ought to be enough of a variety to take care of every conceivable requirement. That such is not the case, however, is illustrated by the fact that small tool manufacturers are annually making thousands of items of tools not listed in their catalogs, and must continue to do so as long as their customers insist on having them.

Standard vs. Special Tool

It is conceded that there are numerous instances where special tools are necessary; but the statement is made advisedly that in many shops from 40 to 60 per cent. of the work now performed with special tools could be equally well performed with standard tools, and at a much lower tool cost. To accomplish this it would be necessary, however, to educate the designers of both the manufactured article itself, and of the various holding and locating fixtures, to the importance of adapting their designs to the most economical uses of tools. Instances are numerous where no end of troubles are encountered in machining because the designers have paid more attention to the purely technical side of design than to the practicability of performing the various machine operations specified.

In the production of many manufactured articles the cost of perishable cutting tools, such as drills, reamers, and milling cutters, represents a large percentage of the total productive cost. As a consequence the question of efficient and long-lived tools has come in for considerable attention. The present tendency, however, seems to be toward the use of special tools where an increased production is desired, or where trouble is encountered. This is believed to be a fallacy in a great many cases. For if a little time and effort is expended in adapting the conditions, such as surface speeds, chip thickness, and holding devices, it is often found that equally good or better results can be produced with standard tools than with special tools, although the latter must be obtained at a much higher price.

In addition to the higher price of special tools, it must be borne in mind that these are only made up in quantities as specified by the user. Hence the source of supply is restricted, and deliveries are subject to delays. Standard tools, on the other hand, can be purchased on the open market and can usually be delivered from the manufacturers' stock.

Relative Costs

Standard tools which are carried in stock by both manufacturers and dealers can naturally be made up in fairly large quantities. Usually from about five hundred to ten or twenty thousand of each size and kind can be put through the factory at one time. This means that many of the benefits accruing from quantity production are realized. There is little time lost in setting up the machines, operators become more efficient on repetition operations, and in many instances it is possible to utilize multiple equipment and other time-saving devices. The non-productive overhead incidental to every order is also spread

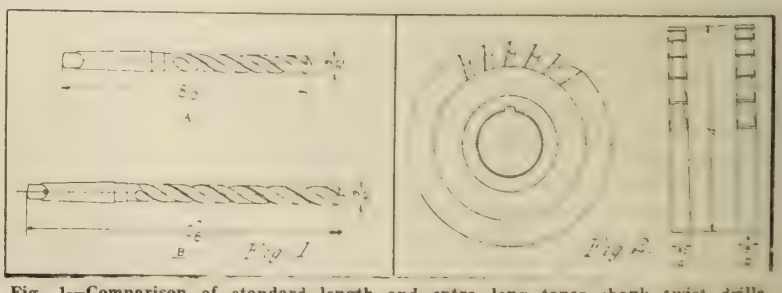

Fig. 1—Comparison of standard length and extra long taper shank twist drills.
Fig. 2.—Standard and special size milling cutters.

Extract of a paper prepared by the author for a recent meeting of the American Society of Mechanical Engineers.

over a great number of pieces, so that the amount chargeable against each piece is very small. All these conditions combined result in a low unit cost.

Compare this with the cost of producing special tools. These are as a rule ordered in small quantities ranging from one to ten or twenty pieces. Highly skilled all-around machine operators must be employed for this class of work. There is just as much time lost in setting up each of the various machines for one piece as for one thousand or ten thousand. There is no opportunity of using multiple equipment on such small numbers of pieces, nor do the machine operators acquire any increased efficiency from repetitions. Non-productive overhead expenses are nearly as high for one or two pieces as for several thousand. The difference is that in one case these expenses must be absorbed by one or two pieces, while in the other case they can be distributed over a very great number. It is obvious how this will affect the respective unit costs, and eventually the price at which the tools must be sold.

Concrete examples of comparative costs will perhaps illustrate the point more forcibly. Let us compare the two twist drills A and B, Fig. 1. Both are 19/32 in. in diameter and of identically the same design throughout except that drill A is of standard length of 8½ in., while B is 2⅜ in. longer, or 10⅞ in. Five hundred of the drills A were made at one time, this being a standard size. The drills B, being special, could be made only in quantity as specified by the customer, in this case six. The direct labor cost of A proved to be only 38 per cent. of the corresponding cost of B. Adding the non-productive overhead, chargeable against the respective orders of which these drills were a part, the total cost of the standard drill A was found to be but 21 per cent. of that of the special drill B.

Representing this in another way, we may say that the increase in length of B over A was 28 per cent., while the increase in cost was 480 per cent.

Similarly, we may compare the two milling cutters C and D, Fig. 2. The special cutter C is slightly smaller than the standard cutter D, yet, owing to the quantities manufactured in each case, the total cost of the cutter C was found to be 270 per cent. higher than the corresponding cost of D. These are but ordinary illustrations of conditions encountered by every tool manufacturer.

Necessarily the cost of producing must be reflected in the cost to the consumer. Pursuing this line of thought, it becomes evident that the high cost of special tools is eventually levied against the manufactured articles on which the tools are used, and in turn is passed on to the purchaser of these articles. Let us suppose that a certain operation requires a special milling cutter costing $30 and that the life of this cutter is 4,800 pieces. If we are able to adapt this same operation to the use of a standard milling cutter of approximately the same dimension we shall have effected a considerable saving. This latter cutter can probably be bought for about $18. The tool cost for one operation is then reduced from $6.25 to $3.75 per thousand pieces. With a great number of machine operations on which such savings may be effected, it is easily conceivable that the results may mean the difference between a possible business loss and a tidy profit at the end of the year.

Elimination of Special Tools

It has already been stated that the total elimination of special tools is impracticable, for there will always be conditions now and then where a standard tool cannot be used; but there can be no doubt that the number of special tools used in the average manufacturing plant, with a little foresight, can be greatly reduced. Engineers and designers responsible for the design of both the manufactured product and of the various jigs and fixtures, must be brought to realize the great economic advantage of standard tools over special tools. Especially is this true where production of large quantities of duplicate parts are involved.

A jig or fixture is a comparatively permanent thing, while cutting tools are in many cases very short-lived. Therefore a small additional expenditure, in order to adapt such jig or fixture to the use of standard tools, eventually becomes a highly profitable investment. Numerous cases can be mentioned where such simple expedients as the shortening of a jig bushing or the slight reduction in height of some projection on a milling fixture will mean from 20 to 50 per cent. reduction in tool costs for that particular operation, inasmuch as it will permit the use of standard tools.

From the author's own experience in the manufacturing of automotive parts there come to mind, too, several instances where the factory, in order to get out the required production, was compelled to ask the engineering department to alter its designs sufficiently so that practical and economical cutting tools could be used. It is a regrettable fact that many engineers, either through ignorance of, or through failure to attach sufficient importance to, small-tools requirements, are in this way wasting money that legitimately should be used either to reduce the cost of the goods or to pay a profit on the invested capital, as the case may be.

Technical schools and colleges would render a real service to the metal-working industries if they were to include in their machine shop curriculum at least a limited amount of instruction along these lines.

It may be properly argued that some of the tools now embodied in the tool manufacturer's standard list do not represent the highest degree of efficiency, and that there are certain other tools, now regarded as special, which will give better results. This is a sound and logical development of the small-tool industry, a development which should be encouraged through the elimination from the standard tool list of obsolete styles and designs, and the substitution of tools, developed through experience and research, that have proved more efficient under all conditions.

We have, for instance, the matter of numbers of teeth in milling cutters and numbers of flutes in reamers. The majority of manufacturers maintain a fair uniformity in this respect, based more or less on practical experience. However, materials and machine-tool equipment are being developed which in many cases demand numbers of teeth or flutes varying from the old established standard. As a consequence many users of tools are specifying numbers of teeth according to their own pet ideas. Obviously this at once classifies the tools as special, because it is impossible for the manufacturer to anticipate consumers' whims.

It seems reasonable to assume, though, that there is one number of teeth or flutes which in general will work most satisfactorily. It is in cases such as these that standardization becomes important from an economic point of view. If standards can be established, and these adhered to, the consumers will derive great benefits through the elimination of expensive special tools and the substitution of more moderately priced standard tools.

For the general good of the metal-working industries as a whole, a program of standardization should be carried out. Attempts should be discouraged to capitalize by attributing fancied advantages to minor construction details and charging special-tools prices for those which legitimately are standard. Standardization will undoubtedly go far toward the total elimination of such practices.

Reduction in the Number of Standard Tools

It is also believed that a material reduction in the number of tools now regarded as standard can be effected without hardship to anyone. A majority of the tools used in the metal-working industries to-day are made from high-speed steel. They are consequently expensive, due to the high cost of the raw material. When it is remembered that a small-tool manufacturer must carry in stock some 5,000 to 10,000 items of these tools, each in sufficient quantity to care for the possible requirements of the trade, it is easily seen that this imposes on him a large overhead, merely as interest on the investment involved. Therefore, the elimination of a number of items will mean a corresponding decrease in the price of those remaining. Some suggestions are given here, which if followed will accomplish much in this direction. It is at least hoped that these suggestions may serve as a basis for future action. The actual carrying

Proposed Standard for Straight-Shank Drills

out of the changes proposed must of course be left to the tool manufacturers, but they can do so only after the consumers have been educated to the great economy made possible.

Let us first consider the ordinary straight-shank twist drill with which everyone is familiar. In the sizes up to and including ½ in. diameter we find 166 standard sizes listed, as follows:

Straight-shank wire drills	80
Straight-shank letter-size drills ..	26
Straight-shank drills — jobbers' lengths	31
Straight-shank drills — taper-shank lengths	29
Total	166

This does not include the approximately 140 sizes of millimeter drills under ½ in. diameter, nor the various odd styles of straight-shank drills such as tell-tale drills, dowel bits, etc. We are here dealing only with the kinds of drills in general use. The establishing of sizes on existing lists appears to have been entirely empiric, as there are many duplications or near duplications with the fractional size drills. One is unable to find any uniform variation in diameter between consecutive sizes.

The table herewith is an attempt to establish uniformity of variation in diameter, and to eliminate sizes which are thought unnecessary. This will mean a reduction from 166 to 73 sizes.

It will be noted that the old symbols have been retained, but that the amount of variation in consecutive sizes has been arranged roughly in a geometrical progression. Thus we have:

From No. 80 to No. 78, diameter increases approximately 0.001 in.

From No. 77 to No. 57, diameter increases approximately 0.002 in.

From 3/64 in. to ⅛ in., diameter increases approximately 0.004 in.

From No. 29 to ¼ in., diameter increases approximately 0.008 in.

From 17/64 in. to ½ in., diameter increases approximately 0.016 in.

Reamers and milling cutters can be made subject to similar methods of standardization and with equally profitable results. No specific proposals are made, because it is realized that such standards must be created through suggestions from a wide field, and through careful consideration and discussion of the suggestions offered.

Tolerances and Nomenclature

The British Engineering Standards Association in 1920 published their Bulletin No. 122, entitled British Standards for Milling Cutters and Reamers. From the introduction to this publication the following is quoted:

"The standards herein contained have been arrived at as a result of conferences, research, and direct co-operation between the small-tool makers, machine-tool makers, and users of this country, at whose instance the work was undertaken....."

An examination of the work done by the British engineers reflects their desire for uniformity in both design, tolerance, and nomenclature. Much of the material could probably be bodily adopted for us in this country, while some of it would necessarily have to be changed to suit our own conditions. We all recognize the desirability of having definite limits established. It seems that as far as reamers are concerned there would be an excellent field for co-ordination with the existing standards of tolerances on shafts and holes.

Uniformity of nomenclature is particularly desirable for the sake of avoiding confusion and loss of time. We have frequently had cases where a customer will order some sort of a tool we never heard of before. When we of necessity ask for further particulars, it is found that a standard tool is wanted, but that a local term is used for designating the same. On the whole it is believed that the engineering societies in taking up this question of standardization of small tools will perform a service to the manufacturers of tools; but more particularly to the users.

In the end it is of course the consumer who pays the bill, and if through standardization this bill can be reduced, we shall have made a step forward in the march toward the goal of economical manufacturing.

EIGHT-HOUR DAY ADVANTAGES

(Continued from Page 15)

and labor turnover and industrial accidents.

Improved spirit and co-operation of workmen.

More exact adherence to instructions as to working methods.

It was found that there were 300,000 wage earners in the United States working on twelve-hour shifts who with their families numbered more than one million persons. No technical difficulties have been encountered by the great majority of plants which have changed from a two to three-shift operation. The seeming disadvantage of having three men instead of two responsible for a given product, process or equipment is overcome by standardization and by using precision instruments. The effect of the eight-hour as compared with the twelve-hour shift operation on the quantity and quality of production, absenteeism and industrial accidents have been satisfactory where good management and co-operation of labor have been secured. A comparison of wage rates shows a general tendency to increase the rate per hour under the eight-hour shift so that the daily earnings will be the same as they were before the change.

The United States Steel Corporation employed approximately 70,000 twelve-hour employees. Altogether there are perhaps 150,000 wage earners in the entire steel industry on twelve-hour shifts. The twelvehour day is strongly established by custom in the iron and steel industry, but recent progress has been in the direction of a shorter day as well as in a reduction of the proportion of men on duty seven days a week.

LIFT-TRUCK PLATFORM

A platform for use with elevating trucks, and which combines both wood and steel in its construction, has been placed on the market recently. The top of the platform is made of wood anywhere from 1¼ to 2 in. in thickness. The wood top is fastened to the steel legs by means of flat-head bolts, set flush. The legs are made of heavy gauge flanged steel plate with vertical ribs to prevent buckling. The lower flange which rests on the floor is wide to provide a good bearing and prevent injury to the floor. The upper flange is extended up around the ends of the planks. The platform is designed for heavy service. The load carrying capacity is increased by the overhanging portion. These platforms are made by the Barrett-Cravens Co., Chicago, Ill.

Practical Ideas From Practical Men

REPETITION WORK IN SMALL QUANTITIES

By G. Blake

In the motor cycle trade the parts which are likely to wear out and replacements are generally made in large batches; for example, valves, valve guides, pistons, gudgeon pins, bushes, etc. The manufacturing of these and other items in large batches permits an efficient layout of jigs and tools so as to produce the work at a minimum cost, while this is the best way to deal with work in large quantities. On the other hand different means have to be adopted when the work is in comparatively small quantities of, say, a gross and under. We recently had an order to make a gross of bushes for motor cycle connecting rods and at a cut price which did not allow any margin for tools, etc. How we tackled the job may be of interest.

Fig. 1 shows the bush which was made from cored gun metal sticks 12 inches long. The equipment available in the shop was one 4¼ inch and two 6 inch lathes and a pillar drill. The first operation, parting off to length, was done on one of the 6 inch centre lathes, using a self-centring chuck to hold the work. The rate of production was 25 per hour, at 8c per hour, boy labour. The second operation—drilling, reaming and recessing, was also done on the 6 in. lathe. Holding the bush in the chuck, the drilling and reaming was performed from the tailstock, and the recessing on the cross slide with a small boring tool. The rate of production was 8 per hour at 8c per hour.

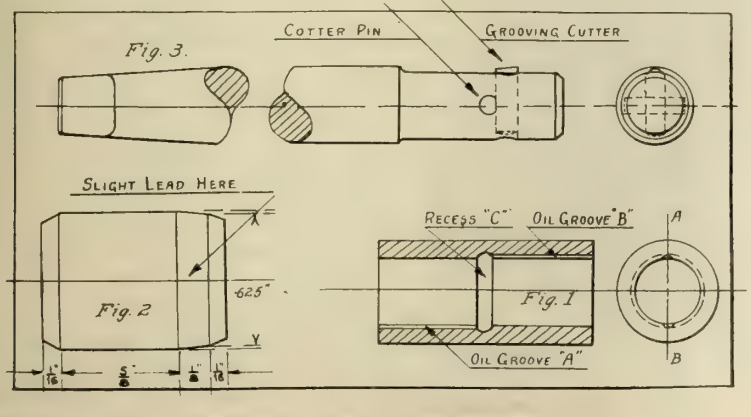
Difficulty was experienced in reaming the bore to size as it was discovered, when trying the gudgeon pin in the bush, that the bore was too small, the diameter of the pin being ⅝ in. + .005 in., and, as we had only a standard ⅝ in. reamer, our trouble was how to make the bore the correct size and at a small cost. As we had no likelihood of getting a repeat order, to grind down a 11/16 in. reamer was rather costly, as it would be of no use for other work. We overcame the difficulty in the following manner:

A small cast steel plug was made as shown in Fig. 2 and turned to the dimensions given and hardened dead hard, and then very highly polished. The tapered end of this plug was now inserted in the bush (after it had been reamed and recessed, etc.) and pushed through on the pillar drill, using it as an arbor press. This method proved very successful, and, in addition to making the bore of the bush the correct size, it produced a highly polished surface, the plug, whilst being forced through, compressed the metal, the result was a better bearing surface and longer wearing life. The writer at first intended using a steel ball to accomplish this end, but was unable to procure one the size desired. It is very essential that the diameter of the plug be highly polished, because if there be any scratches or tool marks, small particles of the bush will adhere to these scratches and score the work. Another point is that the plug must be made absolutely dead hard, or it will soon wear and be of no use. The rate of production on this operation was 40 per hour, at 6c per hour. This sizing operation did not, however, follow the second operation, but it is here mentioned as it was connected with the second operation in the manner described.

The third operation was oil grooving. Referring to the sketch of the bush, it will be noticed that the oil grooves are straight, but they do not run right through from end to end in a straight line; one groove A starts at one end and runs into the recess C, the other groove B starts at the other end on the opposite side and runs into the recess C.

A ⅝ in. dia. boring bar with a small cutter was used to cut these oil grooves. Fig. 3 illustrates the idea. Using the pillar drill as an arbor press, the Morse taper end of the boring bar was inserted in the drilling machine spindle, (by the way, the belt was removed to avoid any accident such as the machine starting up on its own) then the bush was located so that the bar would enter the bore, the plain end of the bar acting as a guide when the cutter commenced to cut as it was forced down, pressure being applied with the hand feed lever, the operator easily feeling the pressure relaxed when the cutter entered the circular recess, he would then raise the spindle, turn the bush over and groove the other end—taking care that it was on the opposite side to the first groove. The rate of production was 30 per hour, at 8c per hour, boy labour. The fourth operation was that of sizing the bore already mentioned.

The fifth operation, that of turning the bush on the outside diameter, was performed on the 4¼ inch centre lathe on a mandrel in the usual way. The rate of production on this operation was 6 per hour, at 8c per hour. It will be noticed that the actual cost in labour works out at about 4c each. This figure is high in comparison with the same article, produced in large quantities on automatic machinery, but, taking into consideration the type of machines available and the relatively small quantity, the cost is remarkably low.



Repetition work in small quantities.

BUY SMALL AMOUNTS OF PLATINUM

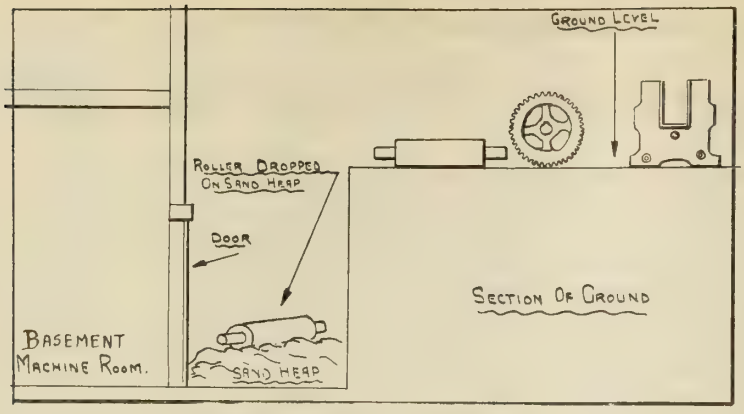
By D. A. H.

A machinist went to work in a garage—such as garages too often are. He asked the proprietor to get him an inch or two of ⅛ in. round platinum so that he could re-tip points. The proprietor was a generous soul and new at the game—he decided that an inch or two was a piker's buy so he ordered two feet. When he got the bill, he fainted for the first time in his life.

AN IMPROVISED C-CLAMP

By D. A. H.

In an emergency a monkey wrench makes a very fair C-clamp. Given some means of turning the screw under a load and one has all the features of commercial clamps, besides having a tool with a much stronger back, with parallel machined sides (when new) and which will go into space narrower than C-clamps. Some monkey wrenches have holes drilled through the knurled head and this is all that is necessary for tightening purposes, others—chiefly larger sizes—have a hex headed screw. For drill press work, the monkey wrench is frequently the simplest way to hold the job but if it is fixed so it can be more than thumb tightened, its value on such work is doubled.



Moving heavy parts to lower levels.

MOVING HEAVY MACHINERY

By G. Blake

It was once the writer's experience to have to move some heavy rubber machinery into the basement of a small factory and there were no appliances to lift the equipment; this is how we accomplished the job. Referring to the sketch it will be noted there was a space between the factory and the ground wall, this was utilized as shown, by dumping several cart loads of fine sand which we had handy. The main frames of the machines were dragged along the ground on rollers to the edge of the parapet and dropped on the sand; this broke the fall of the machine parts. It was then an easy matter to get them through the basement door and into position. The heavy chilled cast iron rollers, etc., were dealt with in a similar manner. By this means we got all the parts into the basement of the factory in a very short time. If the space between the walls had been wider we could have dispensed with the sand and slid the machine parts down on stout planks but unfortunately this was not possible owing to lack of room. However, the sand was quite effective.

BUZZ SAW SPEEDS EXTRAORDINARY

By D. A. H.

A manufacturer of wood and metal specialties was hard hit by German competition. He speeded up wherever he could but on buzz saws, everyone told him that they would not run at higher rates. Still his sawing costs were out of all proportion. Finally he threw precedent aside and began to run his saws faster; with higher speeds, the power feed was greater and production correspondingly increased. He first ascertained from saw manufacturers the safe limit and he learned that there was no limit if he could keep his teeth sharp (the work was all machine fed, and guided, and guarded). To-day he is running 12 in. saws on beech lumber at ten thousand revolutions and other diameters at a like surface speed. More than a year of usage has shown that a saw keeps its edge as well at these new speeds as time honored ones. Production is now satisfactory.

High speeds for saws was entering an untrodden field. There was nothing to go by—there were many things to learn. One thing that troubled was the bearings. This trouble, and lubrication with it, was overcome by building better housings and using a ball bearing. Here also, it was necessary to precede precedent for manufacturers of bearings have no data to guide one as to excessive speeds. Selecting a self aligning bearing of double the calculated capacity solved the problem so that little trouble is now encountered. Saw mandrels have to be very carefully made and the collars and pulleys made out of steel to insure homogeneous metal.

FINDING VOLUMES OF TANKS

By W. F. Schaphorst, M. E.

This chart will be found useful by anybody for determining the volume of a cylindrical tank without doing any figuring. All you have to do is: Lay a straightedge across the chart from known point to known point and the problem is solved. The best way to explain the chart is to give an example—How many gallons will a tank hold whose diameter is 10 ft. and whose height is 20 ft.?

Connect the 10 in column A with the 20 in column D and the answer found in column C is about 11,700 gallons, which is very close. The same act of laying a straightedge across the chart tells us immediately that the volume of the tank is practically 1,550 cub. ft., (see column B). The exact answer is 1,570 cu. ft., which shows that the chart is indeed very accurate although admittedly not absolutely accurate. Most graphical charts of this kind possess a certain degree of inaccuracy but they are useful because of their simplicity. This chart may also be used backwards. For example, if you want to build a tank or buy a tank to hold a certain number of gallons or a certain number of cubic feet, find that "certain number" on the chart and swing your straightedge around it until you find the most economical or most desired height and diameter. A little practice will make an expert of you.

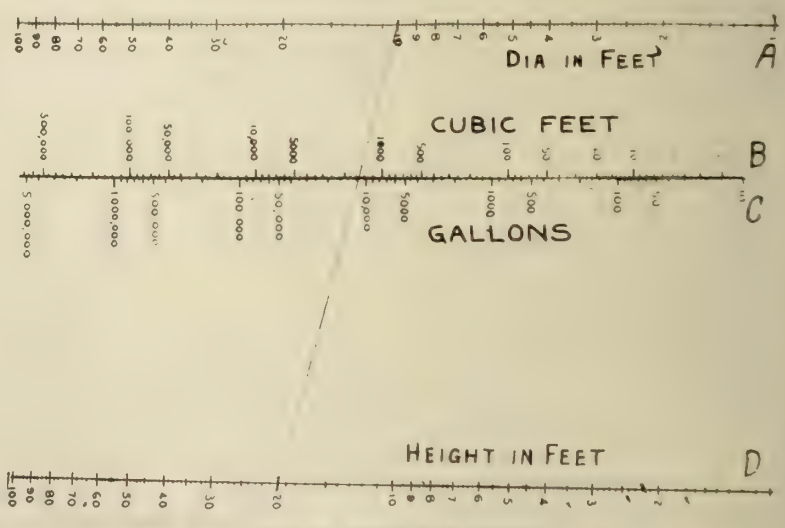


Chart for finding tank capacity.

BOOKLET

J. H. Williams & Co., Limited, of St. Catharines, Ont., with export office at 21 State Street, New York City, have ready for distribution a new and complete export catalogue, showing their lines of drop-forged specialties. These include hand hammers of all kinds—nail, machinists', tinners', riveting, plow, blacksmiths'—and the following wrenches: Stillson (wood and steel handle patterns), screw or monkey wrenches (3 patterns), automobile and bicycle wrenches and adjustable "S" wrenches.

The book is well illustrated and gives full particulars of all the above goods—dimensions, list prices, etc. J. H. Williams & Co., Ltd., is the Canadian branch of J. H. Williams & Co., Brooklyn, Buffalo and Chicago, U. S. A., London office, 56 Ludgate Hill, E. C. 4, known as manufacturers of drop-forged wrenches and machinists' tools, including the "Agrippa" and "Vulcan" brands.

Hangers for iron shafting should be located at the most, 15, 17, 19 or 21 feet apart for 2, 3, 4 and 5 in. diameters. For steel, the limit in each case is about 6 inches more.

New Things in Shop Equipment

VIBRATOR FOR FOUNDRY USE

A recent addition to foundry equipment is a pneumatic vibrator which has just been placed on the market. The device is especially designed for service in core rooms for rapping core boxes when removing the cores to avoid danger of breakage. Sufficient length of hose should be provided to allow the operator to reach any position desired. Air pressure of 20 lbs. per sq. in. is recommended. These tools are made by the Malleable Iron Fittings Co., Brantford, Conn.

BELT-LACE CLOSING TOOL

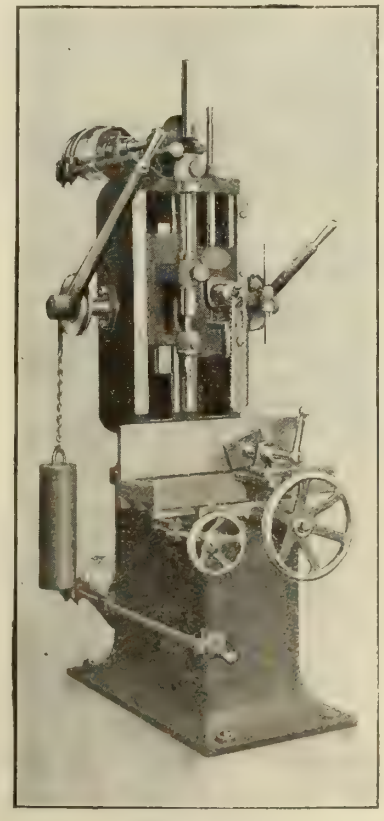
A device especially intended for use in a vise when joining belts with wire lacing has recently been placed on the market. The apparatus is normally held open by means of a spring to allow the belt to be inserted, but when the jaws of the vise are closed the two parts of the lacer are brought together in the proper position to shape the lacing. The standard staggered type of wire belt lacing is used; the hooks are mounted on a card which is placed in the closing device, the belt located by the operator with one hand while the vise is closed with the other. Pressure is used to sink the hooks into the belt and flatten the lacing. Rawhide pins are employed to connect the lacing on the two ends of the belt. They are made by the Detroit Lacer Co., Detroit, Mich.

HIGH SPEED SENSITIVE DRILL

For the particular purpose of drilling and tapping work that is too large for the ordinary sensitive drill, a new design of radial machine has been developed and placed on the market. The rapidity of positioning the drill, together with the ease of operation, minimize the time required between holes, while the high speeds and excess power reduce the actual drilling time. When the table is removed it allows for working on pieces 49½ in. between the spindle and base which has a working surface of 28 x 36 in. The table has an adjustment of 16 in., obtained by means of a ball-bearing telescopic screw. The arm is sensitive in its movement and has an operating range throughout the complete circle. Radial and thrust ball bearings are provided in the column. and the spindle. The spindle is fitted with a Morse taper and has a vertical movement of 8 in. and a horizontal traverse of 28½ in, the latter being obtained by means of a rack and helical gear. The position of handwheel enables the operator to swing the arm and move the head simultaneously with the right hand, while the left is free to raise and lower the spindle and clamp the arm. Friction back gears permit instantaneous shifting from high drilling speeds to slow speeds for tapping or drilling larger holes, the ratio being 4½ to 1. The drive is obtained by means of tight and loose pulleys on the machine, providing both a high and low speed forward and reverse. The belt maintains a uniform tension at every position of the head. The machines are built with either 3 or 3½ ft. arms; the smaller size machine weighs about 2,650 lbs. These drills are built by the Fosdick Machine Tool Co., Cincinnati, Ohio.

MORTISING MACHINE

A chain and hollow chisel mortising machine designed to cover a wide range of operations, has been developed to B. Smith and Son of Bingley, Eng. The chain will mortise at one cut up to 1¼ in. by 3 in., or down to 3/16 in x ⅛ in. x 3/16 in. x ⅞ in. The chisel arrangement takes in chisels from ¼ in. sq. up to 1 in. sq., and by slipping out the chisel this part of the machine may be used for boring round holes. The horizontal table traverse is by rack and pinion. The cross traverse movement is operated by hand wheel and screw. Operator has full control of all levers and handles without moving from his position in front of the machine. The drive is entirely self-contained; a countershaft is fitted in the base of the machine, and from this the drive is taken by belt to the chain mortising spindle.



Mortising Machine.

The driving belt is fitted with a simple device for making allowance for the tension of the belt being kept equal in all positions of the stroke, so that the machine can be operated from any position which may be found convenient in the shop. The chain mortiser has a device for taking up any slack which may develop in the driving belt. The hollow chisel side of the machine is fitted with an independent fast and loose pulley with separate belt fork, which enables this part of the machine to be put out of gear without having to push the belt off when this side of the machine is out of use. All bearings are of phosphor bronze and are provided with ring oiling arrangement. Each mortiser head travels 11½ in. and will make a mortise up to 7 in. deep at one stroke. Machine will accommodate timbers up to 12 in. x 9 in. This machine can be arranged for mortising hubs fitted with dividing heads, and canting arrangements for taper mortises. These machines are marketed in Canada by the A. R. Williams Machinery Co., Toronto.

HEAVY DUTY FRICTION CLUTCH

A friction disc clutch designed particularly for severe service has been developed and placed on the market recently. The former model of this clutch has been equipped on the discs with hard maple blocks that have contact with the friction discs when the clutch is engaged; Non-Burn friction lining is employed on the heavy duty type. These clutches are made in sizes with rated capacities from 5½ to 480 h.p. at a speed of 100 r.p.m. They are of the floating disc type with either one, two or three discs. These clutches are made by the T. B. Wood's Sons Co., Chambersburg, Pa.

NIBBLING MACHINE FOR SHEET METAL

A machine designed along the lines of a rapidly operated punch press and intended primarily for such operations as cutting irregular shapes out of sheet metal, celluloid, fibre and like materials, has been placed on the market recently. It has a cutting capacity of sheet up to 3/16 in. The cutting is done by means of a small cylindrical punch and die operated at high speed, the work being moved in any direction much the same as cutting a pattern out with a jig saw. It is claimed that 18 linear inches per min. can be attained. The amount of

stock cut out at each stroke is governed by a pilot located in the punch. Closed outlines may be worked out by first drilling a hole within the desired space. The movement of a small lever in the ram withdraws the pilot and permits the sheet to be pushed under the punch without disturbing the ram adjustment. By using a template any desired number of pieces may be produced without the operator watching a line. Circles up to 28 in. in dia. may be cut out by use of an attachment. Punches are 3/16 in. dia. and made of special alloy steel, with cutting edges on both ends. These machines are made by A. C. Campbell, Waterbury, Conn.

POCKET MICROMETER CASE

The leather covered metal case here shown has recently been placed on the market by the Brown and Sharpe Mfg., Co., of Providence, R. I. This case protects the micrometer from dirt and injury. The case is lined with plush and its shape adapts itself for pocket use, does not cause the pocket to bulge, and requires very little room. The case is made in two styles, No. 202 for the regular 1 in. micrometer and style No. 203 for the "Rex" 1 in. size. This case offers a good protection for the micrometer and a handy place to keep it.

Micrometer case.

ROLLER BEARING

A bearing in which the rolling action is obtained by means of cylindrical discs is a recent development in mechanical equipment. The periphery of each disc is parallel with its axis and the thickness is half the diameter regardless of the size. It is claimed that this construction, where the rollers have contact on two parallel conical surfaces, that excessive friction and end thrust are eliminated. The several series of rollers are mounted in separate ring cages, as the rollers near the apex of the cone travel faster than those in the other part of the bearing. The rollers are kept complete contact and at proper pressure by means of an adjusting spring. The pressure is automatically controlled, assuring uniform and constant contact with the cone surfaces. The bearings are made in all commercial sizes to accommodate a wide range of work where both radial and thrust loads must be carried. These bearings are made by the Whitney Bearing Corporation, Chicago, Ill.

HAND CENTERING MACHINE

To provide a light efficient machine for accurately centering work, the one here shown has been developed and placed on the market. It has been designed to cover the requirements of the shop having a variety of work which demands quick adjustment to all sizes within the capacity of the machine. While normally equipped with two opposed drill heads for centering both ends of the work in one operation, the machine can be supplied with only one head in cases where all the work to be centered is longer than the double end capacity. The right hand head is adjustable to suit different lengths of work, or it can be removed entirely for occasional long work.

Both heads are normally operated together by the hand lever A which is shown on the right hand head. The drills are advanced by the hand feed lever, with the right hand, until they contact with both ends of the work, which is placed loosely between the jaws of the vise E so that it can shift endwise for this purpose. When contact is secured both jaws of the vise are tightened at the same time by the hand lever F with the left hand, and the work is ready for centering. The drill spindles are mounted in sliding bronze sleeves, provided with ball thrust bearings. These spindles are driven from a constant speed motor, geared to provide a drill speed of 1,200 or 1,800 r.p.m. Changing gears or locking the spindles for the removal of drills, is easily taken care of by knobs B. B. on the top of the drill heads.

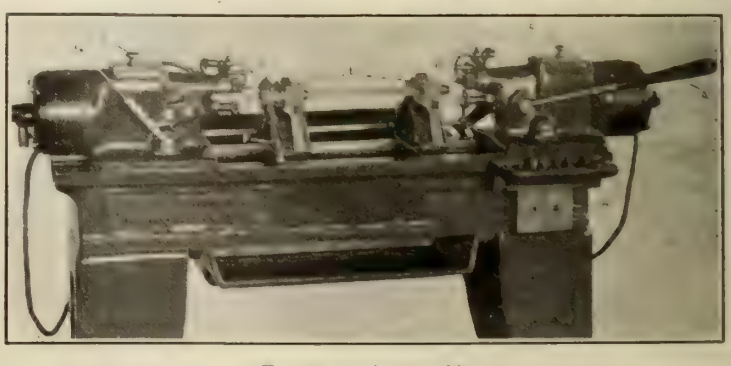
In order to hold the drilling depth to any dimension desired, adjustable stops C. C. are provided which are mounted on the head and bear against the ends of the work to limit the forward movement of the spindles. In certain cases it is necessary to have the center holes the same distance apart regardless of minor variations in the length of work. For this purpose, the adjustable stops are positioned to engage lugs D, D, on the drill heads, thus holding the spindles to a predetermined forward movement.

Two quick acting, self centering vises take all sizes of work up to and including 2 in. diameter. They are adjustable along the bed for different lengths of work, and are operated simultaneously by a single lever. For heavy work up to and including 4 in. diameter, adjustable "V" supports are used. Locking screws maintain the adjustments and one of these supports has a clamp lever to hold the work in place. The work after being centered is deposited in a removable metal tote box at the rear of the machine. Oil drains from this box into the tank and is conveyed to the drills by means of a plunger pump. This pump is connected to, and works with the hand feed lever, so that oil is always supplied to the drills while cutting, without the attention of the operator.

The machine requires a floor space 4 ft. 6 in. by 2 ft. 6 in., and has a net weight of 600 lbs. It is driven by a ¼ h.p. motor operating at a constant speed of 1,700 r.p.m. These centering machines are made by the Pratt and Whitney Co., New York.

PORTABLE ELECTRIC DRILL

A light-weight portable electric drill of simple design has just been placed on the market. The frame is made of aluminum and contains a 1/6 h.p. Westinghouse Motor operating on either alternating or direct current. For small drills the spindle has a speed of 2,000 r.p.m., and this is reduced to 850 r.p.m. when working with drills 5/16 in. dia. Motor windings are coated with a special compound and baked 90 hours, making a solid core This coating adds greatly to the insulating properties and makes the armature practically indestructible from mechanical abrasion. A cool grip is assured by special ventilation through the handle and all parts of the motor. The helical gears are made of bronze with a ratio of 7 5/12 to 1. The purpose of the odd ratio is to provide for better distribution of wear on the gear teeth. Ball bearing thrust is provided. When opening and closing the chuck it is prevented from turning by means of a small spring stop. The switch is located in the handle of the drill in such a position as to be operated by the thumb. The switch is of the quick-break type and is either completely closed or open. It was developed by the Cutler-Hammer Co. These drills are made by the Titan Mfg. Co., Chicago, Ill.



Hand centering machine.

To Develop Empire Trade

THAT there is growing appreciation of the buying power of Canada and other British Dominions is evident from the recent speech at Glasgow of Right. Hon. A. Bonar Law, successor to Lloyd George. To him it appears that one solution of the trade problem caused by temporary loss of European markets, is development of resources within the Empire. For example, Russia formerly supplied a great amount of food. This is now coming from overseas dominions. A carefully thought-out plan in co-operation with these countries should lead to still better trade results within the Empire. An economic conference is proposed at which problems could be discussed.

Such movement as proposed would undoubtedly develop, as an essential, a greater knowledge as to the class of goods required by the different dominions. At the present time, some improvement has been noticed in the mechanism necessary for this purpose. A more consistent use of business papers, and more informative methods in that connection would undoubtedly be found to be effective.

Seven to One Against

IT IS UTTERLY impossible to take any measure of the reader-interest of a free-distribution paper. This was the assertion made by a leading national advertiser at the recent convention of the Audit Bureau of Circulation in Chicago. It explains, in brief, the decisive stand taken against recognition of free-distribution publications, the vote being more than seven to one against.

The Audit Bureau of Circulation, it may be explained, makes available to advertisers authentic analyses of circulation of the publications within its membership. This comprises the leaders among publishers, advertising agents and national advertisers in Canada and United States.

It stands to reason that a reader subscribes for a publication because it represents money's worth. He is keenly interested in its contents and appreciates the fact that the publishers are co-operating with him in his business, that the paper represents definite investment to that end. These are the factors behind reader interest and they make its appraisal a definite proposition.

While it is perhaps natural that publishers of paid-circulation papers should be unanimous against the admission of free papers to A.B.C. membership, it was notable that the most forceful speech at the convention should have been made by a large national advertiser. Reader interest is the basis and test of definite service in a publication. Where it introduces the factor of value received, it develops and maintains a sense of useful purpose and friendly intimacy between reader and publisher which cannot exist otherwise.

Further Deflation Predicted

THERE IS some opinion to the effect that the steel industry at present is in a weak position. In fact, reports from Pittsburgh indicate that the point has been reached when hand-to-mouth buying has developed out of the feeling that prices should gradually decline. Certainly, it is evident that the market is not marked by the heavy advance buying so reflective of upward movements. It is a bearish rather than bullish situation.

Advance in price of railroad steel from $40 to $43 had the desired effect. It brought out large tonnages while the lower figure ruled, and this has ensured winter rollings, but it is stated that the railways were not anxious to begin receiving and paying for rails so soon. Premiums for early shipments on steel have disappeared.

A Canadian observer describes the market as one in which the large interests are jockeying for downward revision of prices. There must be business, and the point has been reached where the possibility of reductions has to be considered; that deflation, rather than further inflation, is in order. Meantime, the industry is going strong at 70 per cent. capacity.

Economists may now say that, after all, the activity in the steel industry was simply an abnormal process by which the depressed area is filling in, and that the law of averages is about to assert itself. In that case, the Canadian recovery may be described as slow but steady and quite healthful.

Aggressive Policy Required

"BUSINESS runs in cycles; business men run in ruts." This observation was given expression by an economist of international repute who recently addressed a gathering of business men. Inclinations were too strongly in the direction of moving, aggressively or otherwise, with the tide, and of assuming too passive an attitude when business went into reverse gear. This made for high peaks and low valleys.

One point was stressed particularly—that the time to advertise, the time for forceful selling, was in periods of depression such as the present. When the cycle was moving above the normal line, when money was plentiful, when production was high, when there was evidence of extravagance on every hand, selling was not the problem that it was when the opposite condition existed. It was then that the most active co-operation of sales forces should be enlisted toward obtaining distribution, when the advertising appeal should be the most convincing. There was a depressed area that must be filled, representing activity rather than stagnation. Though this applied to basic commodities rather than specialties, nevertheless good business in one developed the same condition in the other.

Business men are of opinion that it will require two years to fill the present depressed area to normal level; that considerable re-adjustment in values and prices is still to be done.

Car Repair Program Will Benefit Steel Market

St. Malo Shops Said to Have Two Years' Work Ahead—C.P.R. Sends Cars to U.S. for Needed Material—Dealers Report Demand to be Satisfactory—Weakness in Sheets

ANOTHER ADVANCE IN MERCHANT STEEL PIPE

WHILE the car situation at American steel centres has improved to such an extent that piles of material that had accumulated are being moved, a box-car scarcity is said to be in sight owing to present requirements of the West. There is still a large amount of business on books and buyers are pressing for deliveries. Especially is this so of merchant steel pipes for which there is a very strong demand. Canadian mills have made an expected announcement to the effect that an advance of about two dollars a ton on steel pipe has been made following the recent lead by American mills. It is reported from Pittsburg that relatively little business has been done on the new price, 66 per cent. basing discount which went into effect Oct. 19.

There is a strong demand for sheets in the Pittsburgh market, but it is stated that purchases had been below the rate of production for a couple of months. An easing process has been noted in Canadian sheet markets owing to seasonal interference with roofing operations, and the fact that the market has been well supplied recently not only from the other side but from the Old Country. Bars, shapes and plates were not as active in October as in the preceding month, and specifications on structural are not the feature that they were some weeks ago. On the whole, however, business is good.

The railways, it is reported, are buying considerable material. St. Malo shops of the C. N. R have repair work on hand to keep 500 men busy for two years, and in the meantime other disabled stock accumulates. The C N. R. also has a large amount of such repairs and recently had to send cars across the line for materials needed. All of this means that the day is not far distant when the long-deferred buying activity of the railways must make itself felt in industry generally.

While pig iron markets are not active, they are interesting because of the large amount of English and Scotch iron that is making its appearance in the market. This iron is quite a competitive factor both in Canada and United States at the present time, but dealers declare that it will probably disappear as soon as local furnaces are on a nominal basis of production. Pittsburgh is quoting foundry iron at $29 and $30, valley, with only small lots being sold. It is stated that the whole pig iron market on the other side is lined up for a readjustment to $25 or less.

Montreal reports satisfactory demand for iron and steel, with the exception of sheets, in which the arrival of large supplies and a falling off in roofing demand, have caused a temporary weakness. Conditions generally are moving in the right direction.

Toronto

Nov. 8, 1922.

THAT shipments of steel and other materials are improving and that overdue deliveries have more definite prospect, is the report in Toronto markets this week. This forms a more encouraging background for business depending upon import supplies. Although there have been some seasonal readjustments in demand, as for example in roofing operations which fell off with the arrival of cold weather, dealers point out that demand continues good, and that orders from manufacturing concerns continue to show improvement. It is this steady growth, free from any spectacular movement that is regarded as more healthful and likely to lead to more permanent conditions than would an occasional "flash in the pan."

The most notable change of the week is the advance in steel pipe. Such an advance seemed inevitable following that of the American mills some weeks ago. Costs of production have advanced owing to difficulties in securing skelp and other materials which have been held up by car shortage. It has been known for some time that Canadian mills were confronting a serious curtailment of operations if the situation did not improve. The price increases have been long overdue.

Iron and Steel.—That the market is well supplied with sheet steel and that seasonal conditions are a factor in regulating prices, is evident from the easing process that has been going on during the past few weeks. The stability that marked the summer months has been shifting, and the best example of change is seen in Canada plates dull, 52, which are quoted at $4.90 by firms in close touch with roofing interests while "all brights" are at $5.40. Galvanized 28 are priced at $6.20 to $6.25, while black sheets, No. 28 are listed at $5.10. There is said to be large quantities of British materials coming into the market and that shipment now on the way to Montreal will swell stocks very materially. Reports from Pittsburgh indicate that premiums are practically a thing of the past and that a few weeks will see the leading interest price of $1.85 as the general basis. October has not been as good as September on heavy steel. Specifications do not indicate the same activity in industry generally but it is felt that the level of business for the year has made a very good showing and a great improvement over one year ago. Shipments in import metal have improved. Boiler tubes have also been advanced about 10 per cent. There appeared to be some hesitancy among certain dealers on this move, but this is ascribed to the fact that new stock was on the rails, and available supplies were low. Current iron and steel prices:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 15	3 25
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No 28		5 10
Sheets, blue ann., No 10		4 20
Canada plates, dull, 52 sheets		4 90
Canada plates, all bright		5 10
Galvanized Sheets, No. 28		6 25

Non Ferrous Metals.—Tin continues to be the active factor in this department, and while dealers are quoting $40 to $41, cables indicate the profit-taking has developed in the speculative orgy that has been going on in London and that lower levels are expected. Standard spot declined £1 in one day, while future also lost 17s. 6d. The world's visible supply at the end of October was 22 902 tons as compared with 22 829 tons at the end of September. Some increase had been expected because of increased shipments from the East.

Copper markets, though featureless during the past week, show an improved demand. New York reports tremendous sales both for domestic and export, and it is predicted that prices will become firmer immediately.

Dealers are quoting lead at $7.50 and there has been no change in sheet prices. American Smelting and Refining Company have been advancing prices; in fact a boost of $10 the ton in two days was announced a few days ago owing to a scarcity of prompt metals. This advance will duly become reflected in Canadian quotations. Current prices:—

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	41 00
Lead	7 50
Spelter	9 50
Antimony	8 50
Aluminum	22 00

Old Material.—The dullness in this market is due in some measure to the fact that blast furnace demand is spasmodic and to a feeling that the price movement should reflect that of pig iron and show a downward tendency. Dealers, however, do not concur in this view since their stocks to some extent represent purchases at fairly high levels. Nor are

there over-abundant supplies in some grades, such as No. 1 machine cast iron. There is a fairly good demand in white metals or in those lines that scrap dealers are re-converting into pig iron or ingot form. Dealers are offering following prices:—

Copper, light	9 00
Copper, crucible	11 50
Copper, heavy	11 50
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	7 00
Red brass turnings	7 00
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00

Pig Iron.—This market has been comparatively light of late, and it would appear that foundries are only buying according to present requirements. Some competition is evident between English and domestic pig iron, but authorities claim that this can be only temporary, until Canadian furnaces can adjust themselves. Moreover much of the import pig iron is only for mixing purposes. Steel Company of Canada expect to blow in their second furnace about Dec. 1 on foundry pig.

Machine Tools.—While conditions generally appear to be improving, machine tool business is spotty. Enquiries, however, are encouraging and the feeling is that the phase of the situation is approaching when there will be a steadier flow of business in tools. In the meantime there is a good demand for mill and shop supplies.

Montreal

Nov. 8, 1922.

NO CHANGE in prices has been made this week and the demand for all products except sheet steel has kept up satisfactorily. A serious shortage of certain popular sizes of structural sections exists at the moment and heavy plates have become quite scarce in the various stocks in this district. While relief is expected shortly, conditions at the leading mills in the Pittsburg district are reported to be very bad and it might be quite a while before sufficient tonnage is received here to make the situation normal. Advices indicate that several hundred thousand tons of steel material have accumulated at the mills because of the shortage of rolling stock on the American railways as well as embargoes confining the use of open top cars to coal-carrying traffic.

Iron and Steel.—As an instance of how difficult it is for importers to obtain their requirements, it might be mentioned that last week the C. P. R., sent several empty cars from here to bring on material which was awaiting shipment to their Angus shops but which the mills could not load through their inability to obtain cars. The demand for sheet steel has fallen off considerably. Buyers are well supplied and a lull exists at present in new buying. There is no change in prices, however, and none is expected so far as supplies ex-warehouse are concerned, but some of the American independent mills have reduced the base price of blue annealed steel sheets from $2.75 to $2.60, f. o. b. Pittsburg for prompt shipment, with the "leading interest" maintaining a price of $2.50 base Pittsburg for deferred shipment.

Large importations of steel material including structural shapes, plates and bars were observed on the dock this week representing the cargoes of several steamers which arrived from British ports last week-end. Current prices:

Iron bars, base	3 15 to 3 25	
Steel bars, base	3 15 to 3 25	
Reinforcing bars, base	3 15 to 3 25	
Steel hoops	....	4 00
Tire steel	3 25 to	3 40
Spring steel	....	7 00
Band steel, No. 10 gauge and 3-16" base	3 65	3 75
Small shapes	....	3 40
Sheets, black, No. 28	....	4 75
Shets, blue, ann., No. 10	....	4 10
Canada plates, dull, 52 sheets	....	5 50
Canada Plates, all bright	....	7 00
Galvanized Sheets. No. 28	....	6 50

Pig Iron.—It is estimated that over 6,000 tons of pig iron were discharged from vessels from British ports this week. Reports are that even larger quantities will arrive by succeeding steamers before the close of navigation. A great deal of this iron is finding its way inland, a large portion being for Ontario points. It is not expected, however, that Scotch iron such as Summerlee and Carron will find a permanent place in the Ontario market, and unless something unforeseen happens Canadian iron will again be exclusively used there. There is a good deal of Middlesborough pig iron going into Ontario, but it is not as good as Scotch foundry iron and is merely for mixing purposes.

Discussing the pig iron situation a large dealer states:

"With regard to the pig iron situation, there has, of course, been a considerable quantity of English and Scotch imported during the past few months, and we have sold a fair quantity for Ontario delivery. This is, of, course, special business arising out of the situation in connection with the coal strike and we could not look for its continuation except perhaps in isolated cases. The situation locally is naturally improving and prices we judge, are very close to the cost of import to-day. We can lay down Scotch pig iron to-day at most Ontario towns at about $36.00 per ton delivered, duty paid. this, of course, being for direct import and not from stock. We consider that, by the Spring, conditions will have become quite normal and that it will be difficult or impossible to sell imported pig iron, except at points such as Montreal or nearby places where the import freight rate is very low. British furnaces have, of course, sold a large quantity for export to the U. S. during the past few months, and prices are naturally stiffer as a result. We therefore do not look for any easier prices on the other side at present." Montreal prices:

Algoma, No. 1, car lots on tracks, nominal quotation	38 65	
Summerlee, 30-ton lots, dock	35 00	....
Carron, 30 ton lots	35 00	....
Do., 5 ton lots, ex. warehouse	40 50	....

Old Materials:—The market, both as regards offerings and sales, remains quiet, but average buying prices are as follows:

Copper, light per 100 lbs.	9 00
Copper, crucible	11 50
Copper, heavy	11 25
Copper Wire	11 25
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	25 00
Pipe, wrought	7 00
Car wheels	17 00
Steel Axles	15 00
Machine shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Non-Ferrous Metals.—Conditions are, to an extent, reflective of the New York and London markets. Tin is very firm in price, being quoted here at $40 and $40.50, but any influence causing a reaction in London may result in easier prices here. Business indicates that foundries are fairly well employed. Current prices:

Lake Copper	17 50
Electrolytic Copper	17 25
Castings, Copper	17 00
Tin	40 50
Lead	7 50
Spelter	9 50
Antimony	7 50
Aluminum	22 00

Pittsburgh

November 8, 1922

OPERATION of the steel industry continues at between 70 and 75 per cent. of capacity, the rate being probably close to 70 per cent., although some observers put it at fully 75 per cent.

Supplies of open-top cars continue at the better rate inaugurated about three weeks ago, and are fully equal to moving the current output of materials requiring such cars, while additional inroads have been made upon piles of materials previously accumulated, so that there is not much left of such material. A fresh box car scarcity, however, seems to be developing, as a result of box cars being ordered to move west to help in grain movement.

The finished steel markets, as a whole, are very dull in point of turnover in the open market. The heaviest movement is in sheets, but sheet purchases have been below the rate of production for a couple of months and lately have been considerably below. In merchant steel pipe, there is a very strong demand, but this does not involve very much new buying as there is a large amount of business on books, and buyers are pressing mills for heavier deliveries against these old orders. A little of the tonnage dates prior to the price advance in August, from 71 to 68 per cent. basing

discount. Relatively little business has been done on the further advanced price, 66 per cent, basing discount, in effect since October 19.

Dullness in Some Lines

Bars, shapes and plates are particularly dull. Delivery premiums on these products have now practically disappeared, having been diminishing for more than a month. Several independent mills are now able to make quite early deliveries, although they have some orders on books calling for deliveries strung out to the end of the year.

Tin plate is seasonably dull and is particularly dull on account of price uncertainty. Independent mills have been claiming that there should be an advance from the $4.75 price to $5.25, but buyers are unwilling to contract at an advance when the Steel Corporation has not committed itself. The corporation is likely this week to make a price announcement, and open its books for first half in the case of manufacturing consumers and first quarter in the case of jobbers. The corporation will probably at the same time announce its sheet prices for the first quarter, and in that case there is a question whether the corporation will make an advance. Its prices hitherto have been 2.50c. for blue annealed, 3.35c. for black, 4.35c. for galvanized and 4.70c. for automobile sheets. In the first three months of the year prices were 2.25c. on blue annealed, 3.00c. on black, 4.00c. on galvanized and 4.35c. on automobile sheets.

Several independents are now content to sell black and galvanized sheets at the corporation prices of 3.35c. and 4.35c. respectively, while on blue annealed and automobile sheets they all seem to be able to obtain higher prices, up to 2.75c. on blue annealed and 5.00c. on automobile sheets. Sales of black sheets at above 3.50c. are now somewhat unusual, while galvanized rarely if ever goes at above 4.50c.

Decline in Pig and Coke?

Connellsville furnace coke has ruled quite steadily at $7.50 to $8 for somewhat over a fortnight, following its sharp break from $12. When the market dropped with such celerity from $12 to $8 it looked as if it had enough momentum to carry it considerably farther, but it seems now that a number of furnacemen concluded they had better let well enough alone, and contract to the end of the year at $8 or thereabouts, since the market might perchance regain its $4 loss while there was no chance of its going down another $4. This is the explanation given for the market's steadiness in the past fortnight, in face of increasing production and no material increase in consumptive requirements. For a time after the settlement of the coal strike, when nearly all the merchant furnaces were idle, the attitude of each furnace was that it would get into blast as soon as it could pick up enough coke. With the furnaces that have since gone in, making deliveries on their old sales, with fresh sales in small lots from day to day, there seems to be good balance between production and consumption, and scarcely any of the merchant furnaces now idle are likely to get into blast until consumption increases. Indeed, it is understood that one foundry iron furnace had practically decided some weeks ago to blow in, but now does not intend to do so. A basic iron furnace is considering the matter of blowing in next month, and is meanwhile sounding out the selling prospects in basic iron. In this it must meet the competition of some steel interests, which can make more pig iron than their sales of steel promise to take up.

Bessemer iron continues to sell in small lots at the former price of $33, valley, and foundry remains at $30, valley. Only small lots are being sold, not large enough to cause energetic competition, and the prospect is that if one or two really good-sized inquiries should come into the market the price would decline again. On a small lot sale basic went down $1 to $29, valley, which puts it in more natural relation with foundry iron. The whole pig iron market, of course, is lined up for a readjustment to $25 or less, it being simply a question of how long a time is involved in the decline. Coke, of course, would have to go down also. Its present market of $7.50 to $8 compares with about $3 in January and February, since when there has been a wage advance of over 40 per cent.

Corporation Booked Far Ahead

In September and early in October sheet bars were very hard to buy, and nothing could be done under $40. Now there is no inquiry and there are half a dozen or more sellers. They could be bought at $38 and this price could probably be shaded. Predictions are that sheet bars will not be above $35 for the first quarter of the new year, against $29 in the first three months of this year. Since then there have been the freight rate reductions and the wage advances.

The finished steel market in general is now at the steel corporation prices, with the Steel Corporation booked far ahead in most lines and the independents booked not nearly so far, some of them being rather lightly booked, while the current buying on the whole, is very light. The whole question as to the market, therefore, is how long it will be until independents start cutting prices, the condition being much the same as that which obtained two years ago. Then the independents got down to an average operation of 30 per cent., in January, 1921, against a Steel Corporation operation of 90 per cent., before they started cutting prices. The price concessions began with Midvale, about February 1, and spread to other independents. It seems likely that this time independents will not be content to see their operations go far below those of the corporation.

Heavy Scrap Purchase

The Jones & Laughlin Steel Company has just made remarkably heavy purchases of heavy melting steel scrap, taking about 60,000 tons from five or six dealers, at $21, delivered. This was the quoted market, and on account of the market being soft it was not necessary, as usual, to pay a premium to secure a large tonnage. Delivery specified is to the end of the year, but on account of transportation conditions it will probably take all of January to complete the movement. As the company is now operating all its blast furnaces the inference is that it intends to maintain its steel production at a high rate through the winter.

ENLOW ON SHEET OUTLOOK

A. T. Enlow, president Dominion Sheet Metal Corporation, Hamilton, discussing impressions obtained at a recent meeting of the American Iron and Steel Institute states:—

"There was a great deal of public optimism and considerable private pessimism at the New York meeting, American Iron & Steel Institute. I am afraid there is going to be a soft spot although from present indications it will not be what you might denote 'mushy' especially in galvanized sheets because of the very continued strong tendency of zinc spelter.

"Most of the sheet makers in the States have been asking premiums as compared with the U. S. Steel Corporation price but several of them are now down to the Corporation basis and I question whether they will go any further unless they get desperate and ignore costs because very few of them are making what might be called a reasonable profit and the U. S. Steel Corporation, as you know, have for the seventh consecutive time failed to earn its full dividends, notwithstanding its enormous advantages.

"My idea therefore is, that for the next two or three months, the Canadian buyer will sit rather tight in the saddle and take few chances which may in the end be just as well, and if any of the several dozen things which might happen to upset the world at large do not occur between now and next March, we may expect then to see quite a development in demand but I sincerely hope that the price will remain within a reasonable limit.

"We are continuing our price unchanged but that is due to the fact that we have had a large excess of orders in the last week or so and our price to the Canadian wholesale buyer at the present time is just about on a par with the leading sellers in the U. S. after adding import charges."

Workers' Educational Association of Toronto and district announce their program for the season of 1922-23. This is an organization having for its object the co-operation of labor and learning. Subjects include Economics, English literature and rhetoric, international finance, trade union law, British history, psychology, public speaking, political philosophy.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

Silicon, 2.25% to 2.75%	36 30
Algoma, No. 1, Montreal	38 65
Summerlee, Scotch, Montreal dock	35 00
Summerlee, Warehouse, 5-ton	40 50
Carron, Montreal docks	35 00
Grey forge Pittsburgh	31 27
Lake Superior, charcoal. Chicago	36 15
Standard low phos., Philadelphia	38 00
Bessemer, Pittsburgh	34 77
Basic, Valley furnace	30 00

METALS

	Montreal	Toronto

Profitable Operation of Small Shop Toolrooms

Treating Carbon and High Speed Steels in the Forge—Method of Quenching—Avoid Sharp Corners in Tool Construction—Reforging Undersize Cutting Tools—Making Special Equipment

By H. ALTON

MANY of our large machine shops are invariably equipped with up-to-date toolrooms and manned by a competent staff of toolmakers. The small shop is not so fortunate, generally speaking, but a great deal of real money can be saved if serious thought is given to this department. The writer fully appreciates that it is not possible to assign an appropriation to this phase of the business and purchase a few expensive machines to be devoted exclusively to the production of tools, in scores of shops. Jobbing and contract shops, constitute by far the greater number of our Canadian shops, and these are prohibited from enjoying the luxury of a fully equipped tool room for divers reasons. Nevertheless the successful small-shop-man must always carry in his head that he must be prepared to execute a certain amount of tool work.

Keep Lathe in Good Condition

The tools that necessitate lathe work, can be turned upon any modern lathe that is in good condition. A capable mechanic and a pair of "mikes" on a general purpose lathe in good shape, is able to turn out better work than a less skilled man on a tool room lathe of the first water. Likewise milling and shaping operations can be carried on with general purpose machine tools. A simple tool and cutter grinder is probably the only machine that would be required especially for tool work. The simpler types of these tools, with hand feeds, and minus some of the attachments are not expensive. They consume but little power, need only a minimum of floor space, and, if intelligently used, can be made to pay their way from the moment they are installed.

Use of High Speed Steel

It is often desirable to use high speed steel in special tools. Carbon steel can be hardened in the forge, but it requires a great deal more skill on the part of a tool-smith to handle high speed steel for forging purposes. It is far more desirable to use a miniature oil-fired or gas-fired furnace. Electrical furnaces are also available for this purpose and are very satisfactory. Temperatures from 2 000 deg. F. to 2 400 deg. F. are required to properly harden high speed steel. A pyrometer to definitely indicate these high temperatures is also useful, and if possible should always be part of the equipment. Nevertheless the writer has seen many excellent results from furnaces that were not equipped with these instruments. A good toolsmith knows that the temperatures required by high speed steel are usually about the high limit to which he can coax his furnace, and he also knows by the color of the tool when it is the proper heat. Then, too, a little overheating of the tool is not often accompanied by any serious results if the quenching is intelligently done.

Good judgment in the selection of equipment and a reasonable amount of proper attention to such tools after they have been placed into service should enable the small shop to take care of many jobs of accurate tool and jig work provided a capable man is in charge of the shop. Initiative is the most essential factor in making a paying proposition out of a small machine shop where the staff is called upon to perform a wide variety of work at irregular intervals.

Tools that are symmetrical about a centre line must be immersed with that centre line at right angles to the surface of the quenching oil to avoid distortion. There should be no sharp corners in a high speed steel tool, they should all have a radius, as sharp corners always have a tendency to check or crack in hardening. Form cutters of the single or double cutting edge can best be hardened by only immersing the cutting edges in the quenching oil until the tool has become cooled to a dull red. Tools cooled in this manner are very hard on the cutting edges and are softer in the body which makes them better able to withstand hard usage without breaking.

A good blacksmith will be able to save a great deal of money by softening a special tool that has been ground down to a point where it is useless, and planing same to size again, when it is again hardened and ground. Tools that are used up, as far as their original uses are concerned can be made over into tool bits and applied to tool holders in an infinite number of ways.

Every tool in the shop becomes more useful if the shop fosters a little tool making on the premises. Special tool holders of cast iron are designed and built, simple jigs and fixtures are also forms of tool work, and if designed and built in the shop in spare moments really cost but little. In a number of cases it is good economy to use carbon steel for tools that will only be used a few times at most, and will be required to machine nothing harder than cast iron.

Encourage Initiative

In contract shops a good toolmaker can save his wages many times in making special tools. If a large number of pieces are required on an order, some simple tool will save an extra chucking and may cut the shop cost ten per cent. Skill and ingenuity are never able to show to better advantage than in tool designing and tool making.

Coming again to the tool and cutter grinder, there are innumerable ways in which it can be used to good advantage. Simple fixtures for grinding drills, taps, reamers, milling cutters, etc., always ensure the proper rake and clearance angles and consequently produce tools that cut freely, remove more metal, require less power, etc., all of which are cumulative savings.

Any shop that employs in excess of half a dozen men should always have the nucleus of a tool department. The mechanics take a greater pride in their work and appreciate more fully what accuracy means.

Purchase Fine Tools

There are a number of types of tools that it is not advisable to attempt to make in a small tool room. These are generally—taps, dies, chasers for collapsible dies and taps, solid milling cutters, reamers, gear cutters, etc. Standard tools can usually be purchased at less cost. There is no reason why blades for expansion reamers, inserted teeth, milling cutters, etc., could not be made in a small tool room.

The idea of this article is to convey the fact that it is not necessary to have the highest class of equipment to make many tools, that are commonly required. A modest equipment will often function quite as well. Step by step more intricate tools can be made and equipment added. Simple gauges can be made on an ordinary tool room equipment, and the basis of standardization can be inaugurated in the most modest shops. The days of "cut-and-try" methods have gone and if a shop expects to be successful today tool work must be given attention.

Lackawanna Tubes Limited, Welland, which took over the plant of the Welland Machine and Foundries, and proposed installing a plant to make boiler tubes, has been making slow progress toward operation. The men behind this organization are said to represent large Pittsburgh interests.

News From the Industrial Field

Atlas Iron Works and General Metal Works, Toronto, have been granted an Ontario charter to carry on business as brass and iron founders; capital $40,000.

The N. Slater Co., Hamilton, report that the past month has been exceptionally good, with more business in sight than for some time past.

A. W. Irving, formerly with the Holden Co., and traveller of W. J. Irving, Toronto sales manager of Canada Machinery Corporation, has joined the sales organization of that company.

News comes from London, Eng., that jealousy of Eastern Canadian financiers is interfering with a $12,000,000 project for the development of British Columbia's iron ore resources.

Muskoka Wood Co., Huntsville, Ont., whose plant was destroyed by fire last June, are rebuilding. They will have one of the largest flooring plants in Canada.

Cobourg. — Dominion Wheel and Foundries, Toronto, who have a branch factory here, recently acquired the plant formerly occupied by the Crossen Car Co. They are making brakeshoes and general castings.

H. Bowen, Silver Drill Co., Salem, Ohio, was in Toronto this week calling on F. F. Barber Machinery Co. He is completing Canadian connections and finds the outlook encouraging.

Truman Norton, Wallace Barnes Co., Hamilton, states that business for October showed a wider distribution and a more general buying tendency than heretofore. The record has been very encouraging.

L. E. McKinnon, one of the founders of the McKinnon Industries, St. Catharines, is seriously ill. The plant with which he has been for many years actively identified is very busy at present in the departments having to do with motor car products.

In his report for the past year, the commissioner of patents, Ottawa, reports that 14,274 applications were filed, which was a decrease of 1,172 or eight per cent. from the previous year. Patents issued numbered 7,393, a decrease of 3,759 or over 33 per cent. from the previous year's figures. This decrease, it is explained, is due to the change in the manner of payment of fees. Under the amendments to the Patent Act six months was allowed for remittance of the final fee after notice of allowance, and most applicants took advantage of this change.

Robert S. Harmer, late president of the Sawyer-Massey Co., Brantford, who died in June, left an estate of $341,582.

Shawinigan Foundries, Limited, Montreal, capital stock $40,000, have been incorporated as iron and steel makers and converters and coke manufacturers.

National Radio Corporation, Montreal, $50,000 capital, incorporated to manufacture and market wireless receiving and broadcasting apparatus.

Lewis Mechanical Switches Limited, Ottawa, have been incorporated with $50,000 capital to manufacture and deal in mechanical switches of all kinds.

Pendell Boiler Company, Toronto, have been granted an Ontario charter to manufacture and deal in boilers, piping and general heating apparatus; capital, $500,000.

The Brown Process, Limited, Toronto, capital of $2,500,000, are incorporated to manufacture and deal in chemicals, explosives and other products and to acquire and develop coal, iron or other mineral properties.

More building was done in Windsor, Ont., during October this year than in the corresponding period in 1921, according to figures announced by the building inspector. During the month 113 permits were issued for buildings valued at $277,575, compared with 102 permits last year totalling $240,835. During October 41 residences were constructed at a cost of $194,000.

Building continues active in Galt. During October 19 permits with a value of $90,535 were issued bringing the total for the first ten months of the year to 215 permits with a value of $401,840.50, compared with 179 permits, valued at $483,042, for the same period of 1921. This year's building will amount to more than three-quarters of a million dollars, as a permit has yet to be taken out for the $360,000 addition to the Collegiate, work on which will be commenced before the New Year.

During October permits were issued in Kitchener for the erection of buildings valued at $68,280, bringing the total for the year to date up to $1,946,748. By the end of the year it is expected that the $2,000,000 mark will be passed, thus creating a record. During the month just passed permits were issued for 15 dwellings and 27 garages. In October, 1921, the permits issued called for the erection of buildings valued at $81,400, but the total for the year at that time had only reached a $882,080 figure.

Owing to expansions prosposed by General Motors, Oshawa is looking forward to a residential increase of about 3,000 people.

Efficiency Oil Burners, Limited, Hamilton, capital of $100,000 have been incorporated to manufacture and deal in oil burning, fuel saving and mechanical and electrical appartus.

In Stratford, during October, 34 building permits were issued to a valuation of $18,385, making the total valuation so far this year $678,731. For the corresponding period last year the valuation was $260,184.

Phillips Mfg. Co., Oshawa, are planning to expand in plant and staff at an early date. They are making windshields and curtains for autos, as well as their regular line of picture moulding and frames. They employ 60 men.

Trenton.—Gill & Fortune, Ltd., lumber and timber finishers, who own limits in North Hastings, will equip their plant for local production this fall. Material will be brought from the limits by rail.

Belleville.—Elliott Machinery Co., Limited, have disposed of the British and United States rights to the manufacture of their portable universal woodworkers. The company have been in existence for ten years and in that time have sold 2,000 of these machines.

An addition to their power plant equipment may be called for in connection with proposed expansion by General Motors in Oshawa. They now have equipment consisting of two Leonard boilers and two Detroit stokers; one hand-fed Inglis boiler and two hand-fed Goldie & McCulloch boilers.

General Motors, with Canadian plant in Oshawa and Walkerville, have issued a statement from their head office in Detroit, stating that combined sales by their car and truck divisions in the first quarter of 1922 totalled 71,039 vehicles; second quarter, 135,751; third quarter, 109,346. The nine months of 1922 thus produced sales of 316,136—more than in the entire year of 1921. With conservative estimates for the last quarter of the year, General Motors sales by divisions for the whole of 1922 will be as follows: Passenger cars—Buick, 134,000; Cadillac, 22,000; Chevrolet, 249,000; Oakland, 26,000; Oldsmobile, 23,000; total, 454,000. Commercial cars—Chevrolet, 2,900; G. M. C. trucks, 5,600; Oldsmobile, 1,500; total, 10,000. With miscellaneous cars of 4,355, the grand total amounts to 468,355.

Are You Ready for Your Share?
There's no better time than the present to weed out those worn-out or old-style machines and replace them with real producers. We have, for instant shipment, a huge stock of machines and supplies — each backed by the Williams Guarantee — at prices that will interest you. Present indications point to better times in the immediate future — are you prepared to get your full share?
Our Monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

CANADA GREATEST CAR EXPORTER

"It is predicted that within a decade Canada will be the greatest automobile exporting country in the world," says The Industrial Digest, New York. "Several of the world's largest producers of motor vehicles, according to recent reports, are now handling all their export business from the Dominion, while the largest individual manufacturer of motor cars has for some years filled all orders for the British Dominions and possessions from his plant on the Canadian side of the St. Clair River."

An invention that weighs a railway car while in motion, has been sold for $75,000 by Rev. S. W. Shuford, a Baptist minister of Woodlawn, N. C. The machine not only weighs but registers the initials and numbers of each car. Imagine a machine big enough to admit a railroad car, filled with freight upon its platform. Moving cars in succession come upon it, and when each car is in just the right position—and no other—its weight causes a printing lever to work. The weight is printed upon a card which drops as the car passes off the platform, and leaves another ready for the next car. Mr. Shuford will use the money for evangelistic purposes.

Leather belts, wherever possible, should be made endless on pulleys. A new endless belt will require to be tightened a couple of times, but this is a small job, and then the belt will run for a long time with no other attention than occasionally cleaning and dressing it.

Through confusion with information concerning another plant in Welland, an item recently appeared in these columns to the effect that the Canada Forge Co.'s plant at Welland had been closed for the past two years. This was an error. The Canada Forge Co.'s plant had never been closed down at any time with the exception of a week or ten days in the Spring of 1921.

If there are lacings or hooks that have injured the ends of a belt, new pieces may be cemented on them and there need never be more than one joint in the belt. Should the belt outlast its first installation, it may be cut to a narrower size, may be shortened or lengthened, and the made-over belt is as good as ever for another service. If it is a wide belt it can be cut into several sizes, thus adding to its period of usefulness.

Leslie S. Hall, vice-president Williams Tool Corporation, Erie, Pa., and Brantford, Ont., states: "Business both in Brantford and Erie is improving rapidly. Last month in Erie was the best month we have had in over a year, and this month will be just as good. Besides, we start off next month with a big lot of unfilled orders, which should make it the banner month of the year. In Canada we are now operating about 50 per cent. and the indications are that this will gradually grow until spring when we hope to be running full."

Bulletin CB1 of the Combustion Engineering Co., is descriptive of the burning of bituminous and semi-bituminous coals on Coxe Stokers. In addition to illustrations and description of the stoker, a number of test reports accompanied by curve charts are included.

Bulletin 249 of the Dayton-Dowd Co. is descriptive of their line of centrifugal pumps, and supersedes Bulletin 244 on the same subject. The bulletin is replete with information on the subject of centrifugal pumps, including their design and specifications. A large number of illustrations are shown, both of individual pumps and pump installations.

Inserted Tooth Metal Saws

Greater production and economy are reasons why Machine Shops are equipping their metal cutting machines with Simonds Inserted Tooth Saws. Fitted with High Speed Steel Teeth in an especially fine steel plate, these saws cut rapidly without dulling easily.

The Simonds "00" style Inserted Tooth metal saw cuts only 3/16 inch kerf.

St. Malo Shops Congested With Work; Force of 500 Busy on Car Repairs

Quebec—St. Malo Workshops of the C. N. R. are very active these days. They are in fact congested with work on the repair of locomotive and rolling stock in general, and from information gained here there is an accumulation of work to keep the five hundred employees actively engaged for the next two years. These shops have, of late, received a large amount of new machinery and are still receiving from Ontario and Montreal new equipment and material to fit up the plant with up-to-date machines necessary to meet all emergencies.

The St. Malo Workshops are by no means complete or in keeping with the original plans as agreed between the Government and the City of Quebec, when the latter handed over a large area of property, during the time of the late Laurier administration, worth in money value several millions of dollars. The shops comprise a machine shop, car repair shop, blacksmith shop, power house, round house, and office building, in which is also located the technical department. What is lacking is a brass, an iron foundry, and car building shop, and if these adjuncts were built and equipped, the St. Malo shops would, in all respects, with an enlargement of the present buildings, be capable of taking care of the building of locomotives and repair of rolling stock to meet the demands of the eastern section of the Canadian National Railway System.

It is well to point out, that, when the late Laurier administration agreed to build and centralize railway workshops at Quebec, in connection with the construction and completion of the Transcontinental railway, it had been decided that the shops were to be located at Cape Rouge in close vicinity to the Quebec bridge, with a car yard with capacity of 10,000 cars of every description. All plans had been made in this connection with steamship, deck, grain elevators along the St. Lawrence river frontage and a commodious union passenger station on the Chaplain Market Square overlooked by Dufferin Terrace. The general election of 1911, which resulted in the defeat of the Laurier administration upset all these plans, and these properties, purchased by the Federal Government, were left to fall into decay. Location at St Malo, seven miles from the Quebec bridge, necessitates the bringing of disabled locomotives and rolling stock from the south side of the river over the bridge to the shops for repair. Auxiliary shops to help out the accumulation of work and congestion are built at Cape Rouge, close by the bridge, where there are hundreds of cars now parked, awaiting their turn to be shunted to St. Malo.

The writer paid a visit to the shops to take cognizance of the activities and was surprised to see the congestion of locomotives, passenger and freight cars in the shops undergoing repairs, and the locomotives and cars parked on the sidings awaiting their turn. There were nine locomotives on the pits within the machine shop being repaired and, as there is no round house, there were some seventy others waiting in the open. It is said that there are approximately forty more disabled locomotives in the vicinity.

The car repair shop was congested with passenger cars undergoing repair while in the sidings were large number of box and platform cars waiting. In the meantime, disabled rolling stock will continue to arrive and add to the congestion. New machinery was arriving and the writer was informed that some of the machinery in question, including lathes, grinders, etc., were required to replace machinery which was worn out.

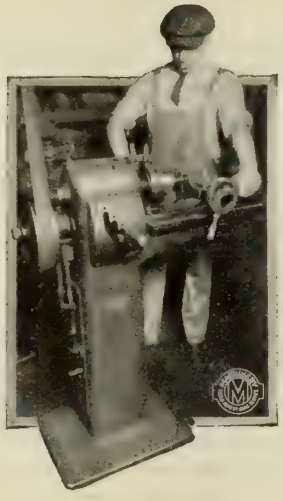
The area of the land purchased and on which the St. Malo shops are built is 160 acres with double that area, adjoining, which permits of an enlargement of the present shops and the building of a brass and iron foundry and a round house so essential for the thorough equipment of the shops. The present machine shop could be extended to allow for ten more locomotive pits, likewise for car repairing shops, etc.

FAMILY BUDGET SLIGHTLY LOWER

In retail prices the average cost of a weekly family budget of 29 staple foods in some 60 cities was $10.28 at the beginning of September as compared with $10.44 for August; $11.82 for September 1921; $15.95 for September, 1920; $11.6 for September, 1917; and $7.83 for September, 1914. The total for food, fuel and rent averaged $20.90 for September as compared with $20.88 for August; $22.37 for September, 1921; $26.38 for September, 1920; $18.57 for September 1917; and $14.33 for September, 1914. The only marked change in foods was a seasonal decline in potatoes, though meats, bread and flour were also lower. Eggs, butter, cheese, evaporated apples, prunes and sugar were slightly higher. Quotations on coal were considerably higher in some cities while in many others it was reported that no anthracite coal was for sale. Wood was also higher. Rent was practically unchanged.

Demand for men to work in lumber camps and railway construction continues, according to reports by the Government employment service. Places could be found for 2,000 to 3,000 men. Fifty or sixty farm hands could also be placed. A number of high-priced men have been located recently. One foundry superintendent was found a position at $5,000 a year; an analytical chemist at $3,600; cost accountant at $3,000; two draughtsmen at $2,500 and $2,000.

GEOMETRIC



and all's well

A Geometric Suggestion will be Worth While

Checking up information with us may give you some valuable information in return.

We have had many kinds of weeks and days—Thrift Week, Spend Week, Save Week, Smile Week, Everybody-to-Church Sunday, Prayer Sunday, Old Clothes Week—month, season—(and for some of us old clothes most of the time.)

Let us have a Screw Cutting Time of our own now. Let us check up the Screw Cutting. Fill in the coupon, and the canvass will be complete. We may be able to give you some information that will give you unmatched production.

It will cost you nothing to make the check-up, and if it appears that there might be a more profitable way for you to do your Screw Thread Cutting, we will not annoy you with advice. We will make the suggestion and leave it with you.

Buying made easy

By grouping together these manufacturers of Special Machinery, Gears, Gauges, Dies, etc., we are making buying easy for you. Here you have a directory of the firms who can fill your requirements on any of these lines. When you are in need of any of the above, consult the firms listed here

CANADIAN MACHINERY

Buyers' Directory

143 University Ave. - - Toronto

$5 May Save You $500 or $5,000!

You work hard for the dollars you save. Properly invested they can be made to work hard for you. But they must be properly invested.

If you feel the need of a guide to show you how to invest your money to bring you the biggest return consistent with safety; to show you how to avoid the pitfalls of investment; you need THE FINANCIAL POST.

It will give you a personalized investment service. Its articles every week will tell you what you want to know about investing. Its discussion of current business and national problems will give you a new angle on economic and political questions. You will have too all the privileges of the Investors Inquiries Department. You may ask as many questions as you like about your own investment and financial problems—the standing of your broker, and the analysis of particular securities, insurance problems, etc. This service is free to all readers.

Stop losing money on bad investments. Invest $5 now where it may save you $500 or $5,000. Pin a $5 bill to this ad. (or your letterhead), write your name and address and we will send you THE POST for one year (52 issues).

THE FINANCIAL POST 143 University Ave. Toronto

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BLACK & DECKER BENCH DRILL STAND

BENCH DRILL STAND WITHOUT DRILL

$45.00

BLACK & DECKER SPECIAL HALF INCH DRILL

$106.00

ILLUSTRATION SHOWS BENCH DRILL STAND *with* BLACK & DECKER SPECIAL ½" DRILL

COMPLETE AS SHOWN

$151.00

The bracket supporting the drill may be raised or lowered to suit the height of the work and may be swung entirely around the post, which is a big advantage in locating the hole and for handling large jobs and odd shapes. The bracket is secured in position by means of a hand screw.

YOU can always tell a good mechanic by his tools. He never buys inferior tools because they are cheap, if he can avoid it. But if he is a good business man as well as a good mechanic he guards against unnecessary expenditures.

In most shops a portable electric drill is absolutely indispensable and a drill press often necessary. Good mechanics everywhere are using Black & Decker Portable Electric Drills; and to make it possible for them to have the advantages of a drill press at minimum expense we have produced the Black & Decker Bench Drill Stand.

The Black & Decker Portable Electric Drill can be mounted in this stand in a few seconds and dismounted just as readily. The Stand sells for only a fraction of what it would cost to install a drill press.

The Black & Decker Post Drill Stand is similar in all respects to the Bench Drill Stand except that it has a longer column and is arranged with brackets so that it can be mounted on wall or post and the drilling table is secured on the vertical column with a hand screw so that it can be raised or lowered or swung around.

MADE IN CANADA

A very substantial reduction in prices has been made possible by the establishment of our Canadian factory.

CREDIT

BLACK & DECKER National Credit Service enables any reliable person in Canada to purchase Black & Decker equipment from his jobber on terms that permit the equipment to pay for itself.

This is the new Black & Decker Special Half Inch Drill, which has created such a sensation in the trade by reason of the fact that it combines Black & Decker quality and an exceptionally low price.

The fact that Canadian Industrials insist upon the finest tools and equipment obtainable makes BLACK & DECKER a natural choice.

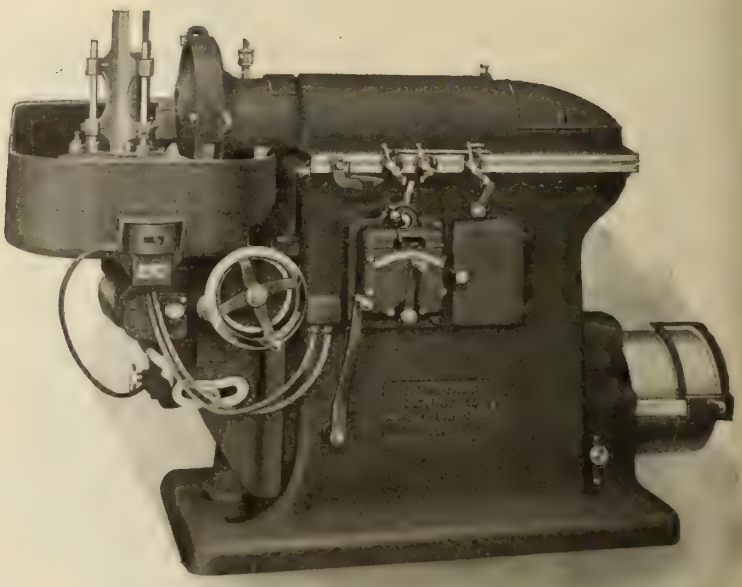
Automatically Chucks

Rings—Ball and Roller Bearings—Collars—Gears—Etc.

Just fill the magazine and take away the finished work with a

HEALD

No. 25



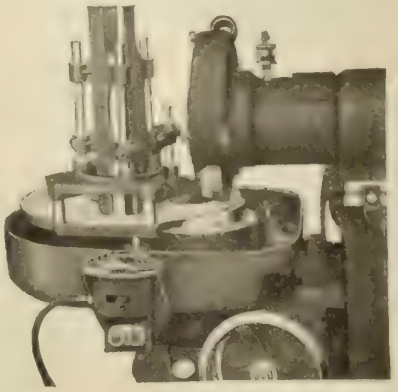
If you are interested in, or manufacture any such parts as rings, ball-races, collars, washers, gears, etc., you should make immediate investigation of the new Heald Rotary Surface Grinding Machine, for chucking by hand will soon be entirely obsolete.

Considering that it only requires filling the magazine and taking away the finished product, no concern can compete, using hand operation, for so many human equations enter when the work is handled by this method that the production in a day's time is decidedly low and uncertain compared to that obtained mechanically, which gives absolute results at a fixed production day after day.

This machine has been designed and built for large production, all of its units being extremely heavy and rigid with moving parts carefully guarded.

The slide is driven by an extremely simple hydraulic arrangement, operated by oil, which makes it possible to get any speed from nothing up to the maximum. The automatic feeding arrangement is made up of a feeding plate with five holes, which can be bushed to take rings up to 5 in. in diameter. As the plate indexes, a ring is moved from the magazine to the center of the chuck.

A two-step cone on the main drive shaft gives two speeds to the wheel, which enables the operator to maintain an efficient surface speed throughout the entire life of the wheel.



Automatic Feeding Attachment

The chuck spindle housing is absolutely tight, which makes it possible to fill it with oil, thus immersing the bearings and gears which drive the chuck spindle.

The diamond, which is located on the chuck pan, can be readily adjusted to true the wheel to give the desired thickness for the ring. Let us go into full details with you, either personally, through our representative or by mail.

Merit Keeps Them on the Job

ON HEAVY tapping like this, P & W Staybolt Taps show their quality. They bite into the work with a precision and ease that makes them favorites with the men who use them.

They are not only good when new, but are heat treated and seasoned to maintain this goodness. That's why you'll find them still on the job when others "just as good" are in the scrap pile.

Pratt & Whitney Staybolt Taps

To meet all your boiler requirements, we build P & W Staybolt Taps in five standard styles, as well as Spindle Staybolt Taps with and without threaded end and also Combined Reamer and Tap to tap continuous hole in the reamer hole of the far boiler plate.

Our reputation for precision and high quality stands behind these tools. Buy them in any of the styles and sizes listed in our Small Tool catalogue which is yours for the asking.
These Taps and our complete line of Small Tools are on sale at our offices in Boston, Philadelphia, Birmingham, Rochester, Cleveland, Detroit, St. Louis, Cincinnati, Seattle, St. Paul, New Orleans, San Francisco.

BLISS

THIS BLISS No. 7 Double Crank Press handles the work formerly done on three or four Power Bending Brakes by six to eight men. Notching, perforating, and forming operations on various parts of metal filing cabinets and lockers, with frequent changes of work and dies.

It has cut out — abolished — the cost of fitting in the final assembly and effected other incidental economies.

BLISS Presses successfully meet every requirement in the sheet metal field. BLISS on your machinery is more than a name, it's a guarantee.

Thoroughbred Springs

RAYMOND SPRINGS—

are in every sense "Thoroughbred Springs." They owe their superiority to careful, painstaking creation by experts, whose knowledge of spring requirements comes from an intensive study of the subject for many years. In addition to this, even smallest details of their manufacture are given the same scrupulous care as obtains during the scientific heat-treatment which imparts to RAYMOND SPRINGS that attribute which places them in the "thoroughbred" class.

There is a RAYMOND SPRING for every purpose.

ARMSTRONG

Bent Tail Lathe Dogs

They Stay With the Job

With Headless Screw

With Square Head Screw

Canadian Agents:
A. R. WILLIAMS, Toronto
WILLIAMS & WILSON, Montreal

The specially tough grade of open hearth steel from which these dogs are drop forged gives to them the stiffness and tensile strength so essential in a good lathe dog. They are designed to stand up to the severest work—moreover, they do so.

The screws are made of alloy steel, hardened at the point, the improved shape of which renders them less liable to "flange" or upset.

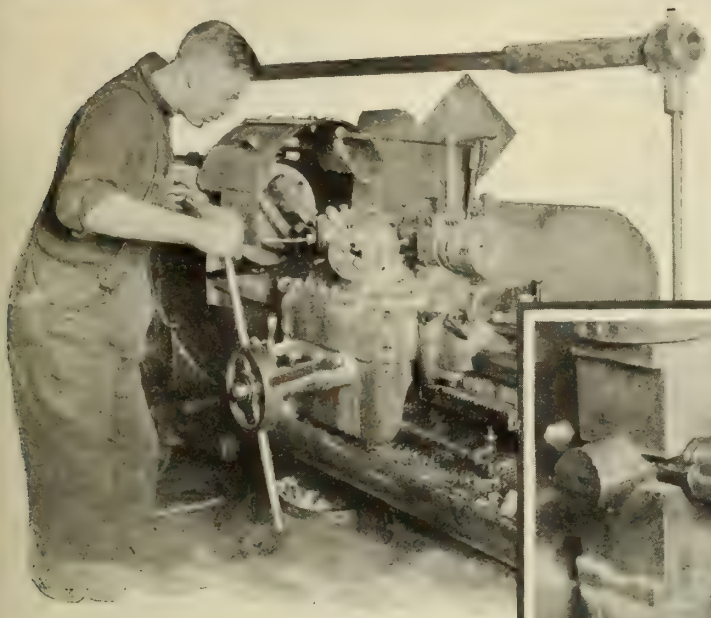
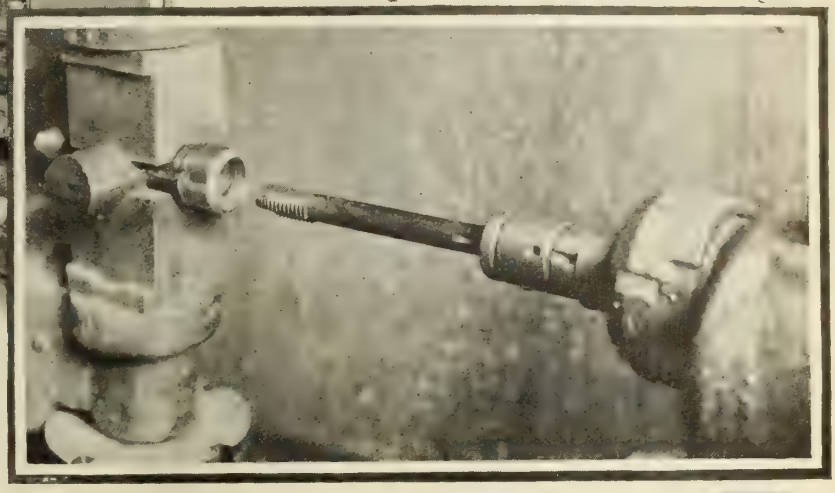
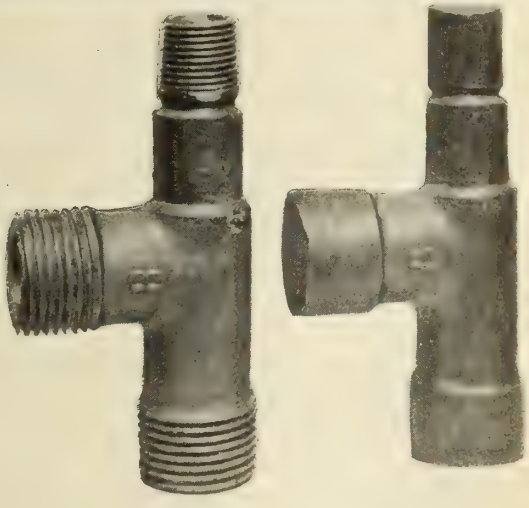
GTD *Little Stories of Real Production* GTD



Will a "Gun" Tap Stand Punishment?



Steel Forgings 5 Seconds per Hole 500 Holes per Grinding!



They say that "in the dark all coons look alike," and doubtless in a catalog or showcase it's hard to see the difference between the *original* spiral-pointed tap (the GTD "GUN" Tap) and an ordinary spiral-pointed tap which copies the *appearance* of a "GUN" Tap.

But out on the job—against the cold light of production demands—"GUN" Taps stand out by the way they stand "punishment." On the J & L pictured above, a "GUN" Tap is used to tap a 5/8 in. hole 1 1/8 in. deep (eleven threads) in a forged steel compressor drum. This tap, working under severe strain (5 seconds per hole), was selected after many ordinary taps had failed, and for four years has justified the confidence of a well-known New Jersey concern (name on request).

The "GUN" Tap, famous for its easy, shearing cut, freedom from clogging and breakage, and its sustained accuracy, will surprise you by outlasting several ordinary taps. On this job, 500 holes are tapped before regrinding—and it's good for an indefinite number of grindings.

Remember the "GUN" is the *original spiral-pointed tap.* Its superiority is characteristic of GTD small tool service all along the line.

MADE IN CANADA

WILLIAMS' SUPERIOR

DROP-FORGED HAMMERS

Are dependable tools because:--

Their heads, drop-forged from a special grade of tough steel, carefully hardened and tempered, neither crack, chip nor splinter.

They are fastened most securely and solidly to the handles—can't work loose—can't fly off.

Their handles are made of the best grade of clear, straight-grained hickory, flared at the grip to prevent hand-slip.

The weight and length of each tool are properly proportioned to give perfect balance, and, hence, increased striking power.

Williams' quality Hammers of all kinds and sizes. Catalog on request.

"The Drop-Forging People"

45 Thorold Road - St. Catharines, Ontario

MADE IN CANADA

"CANADIAN"
HAND POWER PUNCHES AND SHEARS

All Canadian hand power punches and Shears are made with "Armor Plate" frames.

This frame construction consists of a rolled steel plate having a tensile strength 7½ times that of cast iron. This strength permits of a machine much lighter and more compact than is possible with either cast iron or cast steel.

Let us know your punching and shearing requirements. We have an "Armor Plate" machine for the service. Remember our Armor Plate line comprises power operated machines as well as hand power.

AN ACCURATE TOOL
for Inside Measuring

Here's the tool for accurate, inside measuring—a Brown & Sharpe Inside Micrometer which measures directly in thousandths.

This reliable tool shows the exact size quickly—eliminates all uncertainty—speeds up accurate work.

These advantages, which you have found already in Outside Micrometers, are good reasons for using Inside Micrometers on accurate, inside work.

Ask your Dealer to show you this tool

For the many accurate jobs which must be right to a thousandth, Inside Micrometers are indispensable.

With this tool you can quickly tell exactly how much metal remains to be removed. This is a great help, especially when the work is nearly to size.

Inside Micrometers give you the facts essential for first-class work.

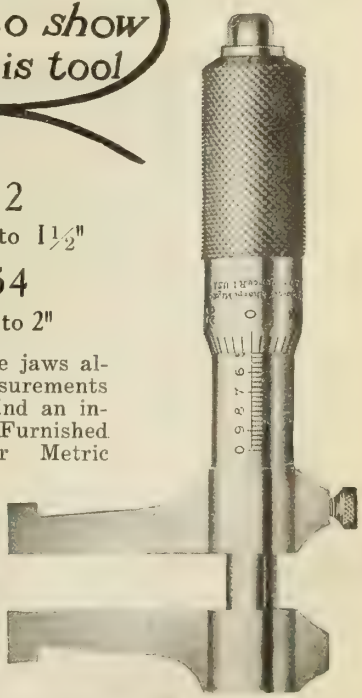
Let this Brown & Sharpe Tool help you on accurate, inside work. Buy your kit one of these Inside Micrometers—it will add to your reputation for good workmanship.

Insist on the name BROWN & SHARPE

No. 252
measures ½" to 1½"

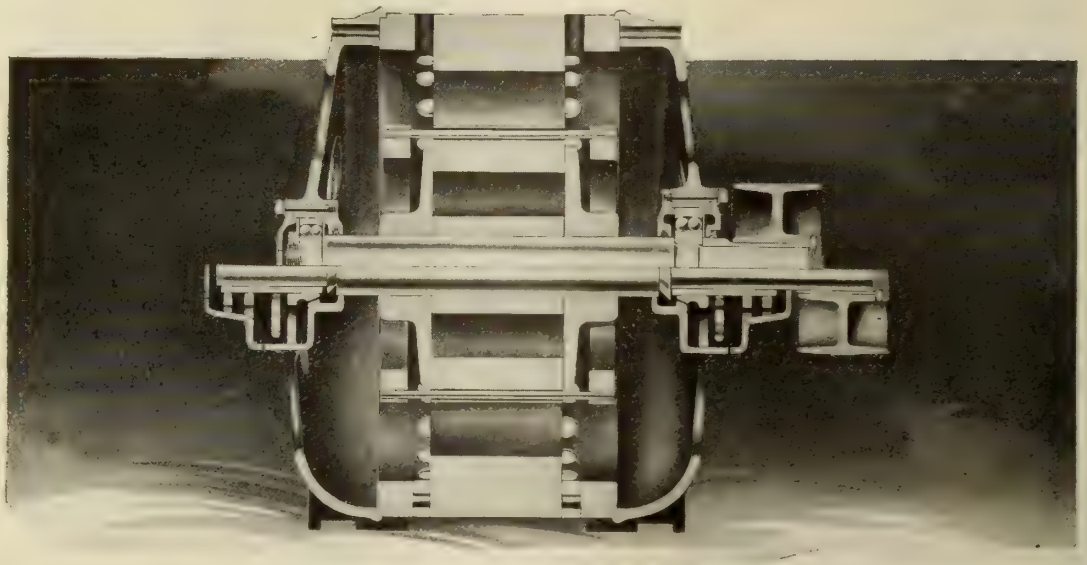
No. 254
measures 1" to 2"

The shape of the jaws allows inside measurements to be made behind an inner shoulder. Furnished in English or Metric Measure.



BROWN & SHARPE MFG. CO. **PROVIDENCE, R.I., U.S.A.**

SKF



Self-Aligning Ball Bearings

Shorten your Motors - Extend their Market

The more compact a motor can be made, the greater the field of its application, for space restrictions—especially in the case of individual motor drive—frequently govern the make of motor selected.

When **SKF** marked self-aligning ball bearings are used, as compared with plain bearings, the over-all length of the motor can be decreased from 10 to 27 per cent. The natural outcome of this increased adaptability is a larger market for your motors without the necessity of quoting on special motors of uncertain performance in cases where space is restricted.

Motors equipped with self-aligning ball bearings are free from hot bearings and misalignment troubles and armatures cannot strike the field structures. No renewals or adjustments are required, and lubrication and maintenance costs are reduced 80 per cent. Bulletin No. 113 gives detailed information.

Accurate Production on Horizontal Boring Machine

Special Fixture Facilitates Setting of Work—Indexing for Position—Face Milling Automobile Crank Cases—Many Operations on Milling Machine Frame Performed at One Setting

FEW MACHINES can be as readily adapted to a wide range of unusual operations as the horizontal boring machine. The vertical adjustment provided on the spindle head and the horizontal movement of the table in two directions, as well as the angular movement when fitted with a revolving work table, supplies ample solution for machining problems that would be very difficult, if not impossible to perform in any other way. To obtain the maximum efficiency of any machine it is frequently necessary, on the part of the plant superintendent or operator, to exercise considerable initiative in devising accessory equipment to facilitate the handling and locating of the work. Fixtures that minimize the possibility of error in machining are frequently of inestimable assistance when the volume of work will warrant their construction.

Cuts shown in Figs. 1 and 2 obtained through courtesy of the Universal Boring Machine Co., while illustrations shown in Figs. 3 and 4, were supplied by courtesy of Pawling and Harnischfeger Co.

An Unusual Job

An example of special interest in the boring of holes in intricate castings is shown in Fig. 1. The illustration shows a large casting 40 in. outside diameter and 8 in. thick. In addition to the centre hole, which is finished in a previous operation, the piece requires machine work on five 8 in. hobs, one 4½ in., and two 3⅝ in. diameter. The 4½ in. and 8 in. holes are all of equal radial distance from the axis of the central bore, while the two smaller holes are closer to the centre and require a second adjustment of the boring bar head or work table. The extreme accuracy of the work may be gathered from the fact that there is no limit allowed on any of the holes, every hole being bored to exact size and its position in relation to adjacent and central hole to specified dimensions. It may be seen that a special fixture has been designed for holding the work. While this fixture was primarily constructed for this particular job, it is more or less general in character, as it may be adapted readily

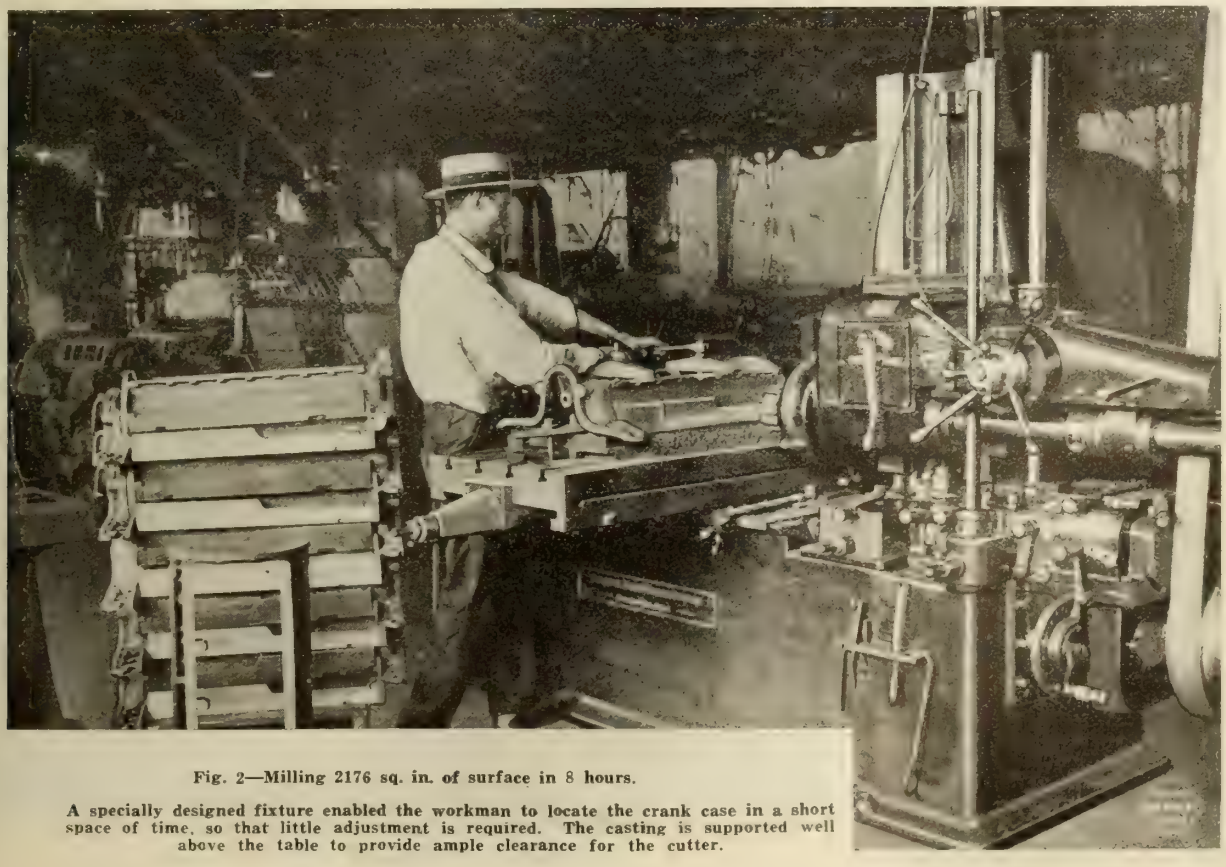

Fig. 2—Milling 2176 sq. in. of surface in 8 hours.

A specially designed fixture enabled the workman to locate the crank case in a short space of time, so that little adjustment is required. The casting is supported well above the table to provide ample clearance for the cutter.

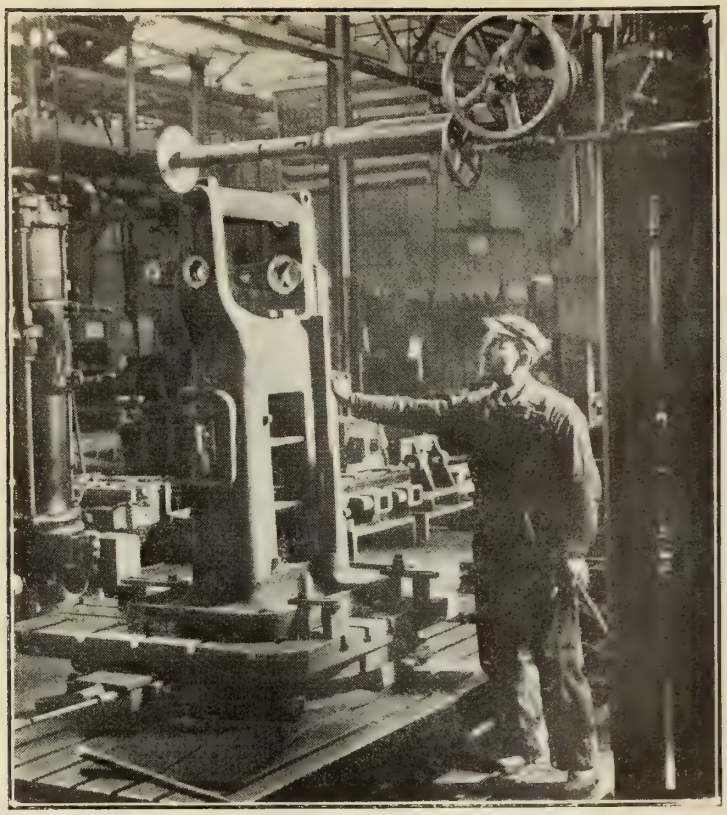

Fig. 3—Performing a number of operations at one setting.

to a variety of similar work within its range, where a number of holes are to be placed at a fixed distance from some other hole in the same casting. The jig consists of a base and two side walls in which a number of holes are accurately located for supporting the boring bar while tools are cutting. All jig holes are reinforced by bosses of ample size to rigidly support the bar under the stress of the cut.

After the central hole has been machined and the casting faced on either side in a large lathe or boring mill, it is placed on a large arbor which is then supported in the main housings of the fixture—the jig having previously been accurately located on the work table in relation to the position of the hole to be bored. After the first hole is bored the casting is indexed to the next position by means of a locating plug placed in the hole just machined and a corresponding hole in the fixture. These castings were machined at the plant of the Bawden Machine Co., Toronto, the production rate being one complete casting, floor to floor, in eight hours.

The machining of surfaces by means of milling, on a production basis, is nowhere more evident than in automobile engine plants. The problem is not only one of quantity but likewise of quality, and accuracy must not be sacrificed to volume output. Fig. 2 shows a horizontal boring mill face milling crank cases at the plant of a large motor plant. Each casting requires machining on two surfaces 21 in. long and ¾ in. wide. Approximately ⅛ in. of stock is removed from the entire 68 sq. in. in less than fifteen minutes. Including the handling and setting up these crank cases are finished at the rate of 16 per eight hours—one every half hour, floor to floor. Accuracy is maintained to the closest limits.

Maintaining Accuracy

In the construction of large machine tools one of the greatest problems is the maintaining of accuracy in alignment of the many holes and locating surfaces on large main castings, that are required to support a variety of shafts and brackets that are indispensable fo the efficient operation of the machine.

The chief difficulty that confronts the manufacturer in regard to the machining of large bed or frame castings is the different settings that are invariably necessary to complete the range of operations distributed on all sides of the piece. The efficiency of any machine may be said to vary inversely as the number of settings required to perform the range of machine operations required on the main supporting castings. In a great many cases the setting-up of the work requires considerably more time than the machining operation, and every subsequent setting after the first hole or surface has been finished necessitates additional care in maintaining accurate alignment of all machined surfaces.

Only One Setting Necessary

Fig. 3 illustrates a large horizontal boring machine sawing the slot in the top of a milling machine frame, this slot providing the clearance necessary for clamping the overhanging arm. All the operations of drilling, reaming and topping are performed at the one setting of the work, the turn table on which the frame is supporting, permitting the machine spindle to operate on all four sides of the casting as well as on top as shown. The various details accomplished at this setting are: bore and ream one hole ½ in. through 5⅜ in. of metal, faced and back-faced; drill one hole ¾ in. through 1¾ in.; drill and tap one hole ¾ in.

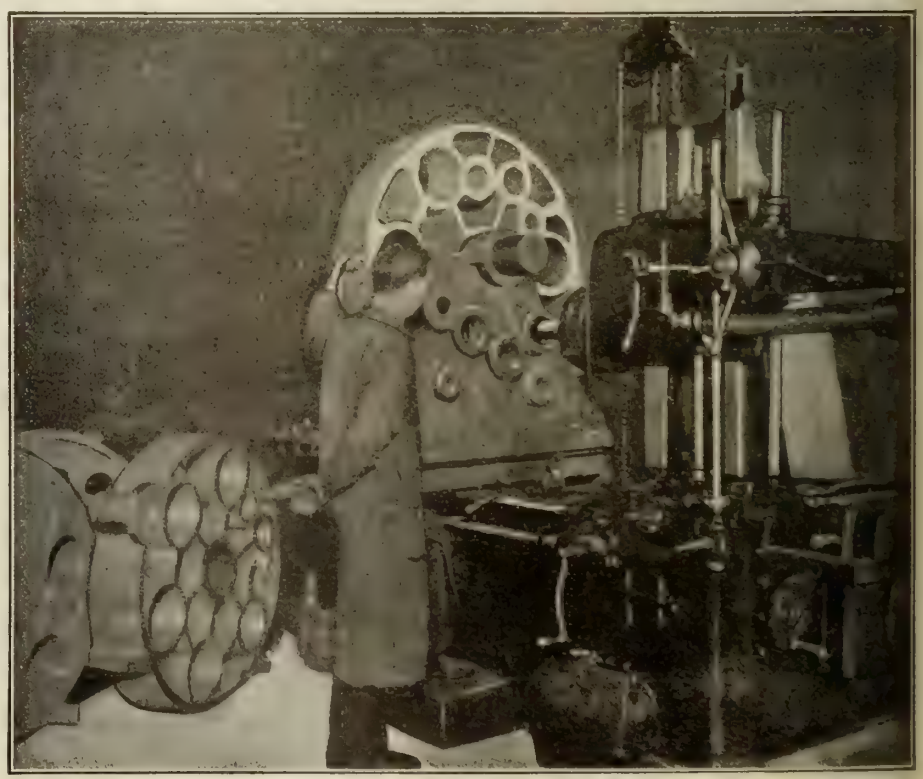

Fig. 1—Accuracy maintained on record production.

through 1¾ in.; drill one hole 7/16 in. through 1½ in.; drill and tap two holes ⅜ in. through 1 in.; drill one hole 11/32 in. through ¾ in.; drill and tap six holes ½ in. through 1½ in.; drill and tap two holes 7/16 in. through 1¼ in.; drill and tap one hole ½ in. through 2 in.; drill and tap three holes ⅝ in. through 2 in.; drill one hole 11/32 in. through ½ in.; mill ⅛ in. slot through 2 in. metal 4 in. long. All of these varied operations, including placing and setting of the work, are performed in 90 minutes.

One Hole a Minute

An example of the adaptability of the horizontal boring machine for the accomplishment of unusual jobs is shown in Fig. 4. The work is the speed ring for a large hydraulic turbine for the Allis Chalmers Mfg. Co. The operation consists of drilling at an angle 720 —1/16 in. hole through 2 in. of metal. The diameter of the ring was 12 ft. and the steel casting weighed approximately 14,680 lbs. Owing to the angle at which the holes were drilled it was necessary to provide special facilities for supporting the work, so that the job could be handled advantageously. The revolving table, which is adjustable to position, was tilted to a considerable angle and the boring machine tipped over 30 deg. off the vertical. The entire 720 holes were drilled in one day, averaging one hole in a little over one minute, including movement and setting for each position. This is about the only way a job of this description could be economically performed.

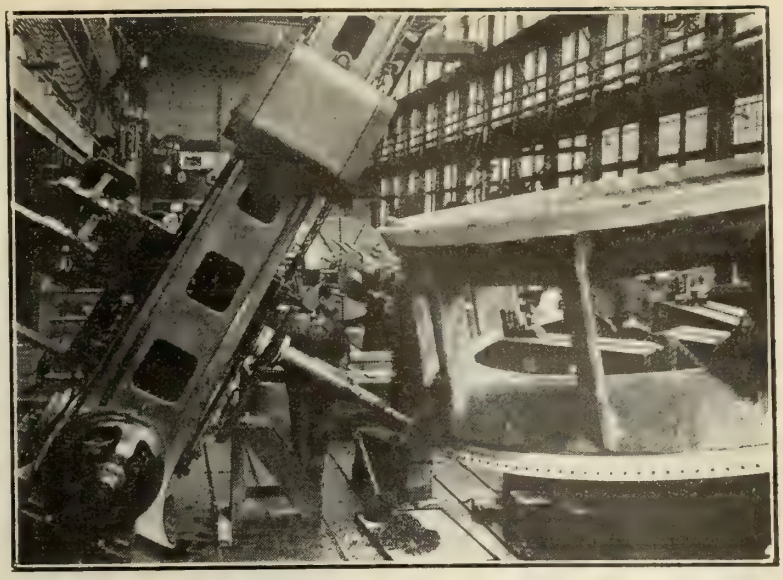

Fig. 4—Adapting the boring machine to unusual jobs.

Requirements of a Good Bearing Metal

THE relative value of a bearing metal is not to be judged by its composition and physical properties alone. Many other factors, which are frequently overlooked, should enter into its selection. For instance, the lower specific gravity of the tin-base metals, and the fact that they can be used to advantage in very thin linings, should make them the logical selection for many bearings in which a lead-base metal is now used.

Again, allowance is very rarely made for the losses which occur in the melting and remelting of many metals. A babbitt of properly balanced composition, which is carefully alloyed from strictly virgin materials, should give very little dross and be remelted without serious loss of either metal or properties. Unfortunately, however, the use of virgin materials in the manufacture of babbitt is the exception rather than the rule, and any apparent saving recoils heavily on the head of the purchaser. The loss in melting babbitts made from reclaimed metals is frequently as much as 6 per cent. This item alone, with a fair allowance for melting cost and overhad, increases the actual cost of the metal by fully 10 per cent., to allow nothing for the sacrifice of bearing properties inevitable to the substitution of reclaimed for virgin metals.

While it is difficult to secure bearings of perfect uniformity from babbitts alloyed in the customary manner, the difficulty is magnified a thousand fold when reclaimed metals are used, and if the purchaser is buying bearing service rather than so many pounds of metal he does not get what he pays for. In service, the most obvious, but by no means most important, requirement of a babbitt is that it should have sufficient strength and hardness to carry the load with a reasonable factor of safety. The physical properties of a babbitt are valuable only in determining that it will meet this requirement and it should be borne in mind that they normally give very little, if any, indication of the performance of the metal in other respects. The compressive strength and Brinnell hardness tests do, however, serve as an excellent guide to the uniformity of metals of the same analysis.

The tensile strength and elongation of a metal are valuable as indicating its ability to withstand repeated shocks and pounds without cracking or fracturing, and are more important than the compressive strength and hardness in metals which are to be subjected to a pounding action or are to be poured into very thin linings. It is when abnormal conditions are encountered that the true requirements of a babbitt become apparent.. In the majority of machines the bearing surfaces are normally separated by a film of oil, and were this condition to continue indefinitely, sufficient strength to carry the load would be the sole requirement of a bearing. There is, however, as will be discussed later, an ever present liability to separation of the oil film which cannot be foreseen or prevented. This breakage of the film may be due to many causes; temporary or permanent failure of the oiling device, the introduction of foreign matter, heavy overload, etc.

Immediately the oil film breaks, the journal and bearing come into contact and heat is generated due to the friction. How soon this heat may become sufficient to cause failure of the bearing depends entirely upon the true bearing properties of the babbitt. As in ninety-nine cases out of one hundred the separation of the oil film is temporary rather than permanent these properties are of extreme importance. It will be realized from the above that the metal is best which most fully combines the following properties:

(1) A tendency to hold the oil film when extraneous conditions are tending to separate it.

(2) A low coefficient of friction, to reduce the quantity of heat generated.

(3) Relatively high heat conductivity, to more rapidly convey the heat from the point at which it is generated.

(4) Ability to continue to carry the load at abnormal temperatures.

A consideration of the requirements outlined above is as essential to the intelligent selection of a babbitt as its more obvious physical properties, and they are even more deserving of the attention of the engineer.

When performing any babbitting in cold weather, or where the space to be filled is comparatively small, it is best to heat the shaft slightly to insure a good job and the box or container should be rough or supplied with hobs or undercut grooves so as to thoroughly lock the babbitt shell in position; a loose babbitt filling is a source of trouble and annoyance. And in all cases keep the contact surfaces perfectly dry.

"Throw Your Heart Across"—Inspiring Message

Sir Joseph Flavelle Discusses Individualism as a Factor in Affairs—Too Much Reliance Upon Social and Political Influence—Problems Solved From Within Rather Than Without

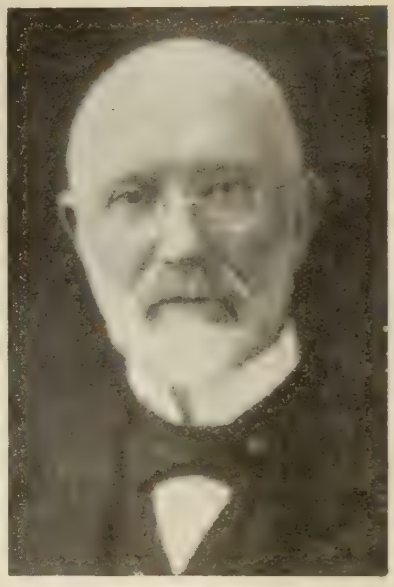
THAT the supreme test of a man consisted in his ability to "throw his heart across"—much as a horseman confronting a difficult venture—was the inspiring message, delivered by Sir Joseph Flavelle, in an address to business paper men on the occasion of the annual meeting of the Canadian National Newspapers and Periodicals Association.

Discussing the subject, "Individualism as a Factor in Affairs," Sir Joseph stressed the point that it was at the end of an undertaking that the real problem generally developed, and that it was then that supreme courage was required. The individualist was one who thought and worked for himself, and his recognition of the principle of relative responsibility made him an important factor in the world of affairs. In the speaker's view the reliance placed by men upon what governments might or might not accomplish, was piteous. Man did his best rowing hard against the stream, rather than in depending upon social or political influence in his behalf. The true destiny of men, as of nations, depended upon certain integrating forces which, as outlined by Lord Rosebery, in addressing the students of a Scottish university, consisted in measured self-control, respect for law and authority, obedience, limitation of desires and application. There was an abundance of vital energy; what was needed was vital control.

Misdirected Organization

Much was heard today of organization in business and industry. It could be developed in such a way as to either build up or destroy a man's individuality. It could be misdirected so as to defeat the purposes for which it was intended. The speaker referred to the very elaborate plans made by the military men of the United States during the war in building up an organization that had shell production as its ultimate objective. Acres of ground were covered with administrative buildings and miles of blue prints were produced showing the relation of departments very much the same as a family tree, all beautifully done. "Yet," said the speaker, "although that organization had a staff of 20,000 men, it never fired an American shell or discharged an American gun during the war." The individuality of the immense machine was not capable of the practical appreciation of the emergency."

In the same way, it was rare indeed that a workman admitted that a problem in his shop might be solved by harder work and more thoughtful application on his part, rather than by the purchase of more equipment or the enlargement of the plant. Rare indeed was it that so-called brotherhoods, unions and societies tended to give free play to the individuality of the man so that he might be encouraged to work toward his high purpose independently, and with the feeling that his destiny involved unflinching personal courage and effort rather than reliance upon outside influence for his advancement. On the other hand, organization might be developed along lines that were most dispiriting to the so-called craftsman. The speaker made reference to the Ford factory at Detroit. Wonderful, in every sense of the word, yet he could not but conclude that it was most dispiriting work to occupy a position beside a conveyor belt day in and day out tightening nuts or boring holes or performing other operation as the different parts moved onward toward completion. He wondered what the destiny must be of those craftsmen who could claim no other accomplishment than their ability to tighten nuts or bore holes. Here was no individuality. Yet the world today was living upon the capital of craftsmanship, representing long years of patient effort.



Sir Joseph Flavelle.

"Canada has had few serious losses to bear. We can accept our moderate discomforts with dignity and restraint. We can secure no relief from heavy taxation. There can be no freedom for years from the drain upon our cash resources through overbuilt railways, now the property of the State, but we have no cause to fear if we play the game with high courage. Whatever happens we must not lose our courage or abandon a sense of individual responsibility and individual effort. There is an honorable place for each man in Canada who does his job as well as he can each day, and that is the way the world's work, which matters, is done."

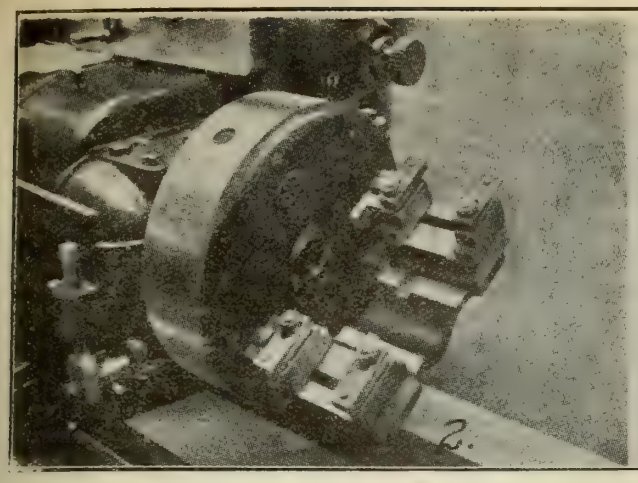
Study Defects From Inside

Another problem that frequently developed in connection with organization was the impression that defects had their origin from the outside and that solution should come from the same direction. It was the speaker's experience that self-examination would reveal that much of the trouble, if not all of it, came from within. He recalled an incident during the war. A manufacturer of munitions complained that, under the terms of the contract, he could not make headway profitably, that his plant was well organized and was in every respect efficient, and that it was useless to try to convince him that the trouble lay within, that there were things going on of which he knew nothing. An inspector was accordingly sent to the factory. He found, as had been suspected, that the organization did not have a grip of essential details within the plant. One workman, it was found, was driving screws into shell boxes by means of a hammer and thus causing a defect which explained why boxes were not standing up on their strenuous trip to the front. Problems within were sometimes obscured by the feeling that the remedy could be secured through outside agency.

Make Something Worth Sharing

Sir Joseph's theory with regard to trusts was that, while he did not think they were capable of much injury to the ultimate consumer by controlling prices, the public was frequently called upon to pay for their ill-advised organization and for the trouble that developed and emanated from within their own ranks. It was these internal problems which often explained the failure of two or more men to agree in partnership who might succeed individually. It was his opinion that unions, sympathetic strikes, the "ca' canny" which set a limit to a man's production, were menaces to society in that they sought to control the spirits and lives of responsible men and restricted their vision to such an extent that individuality was crushed in the

(Continued on page 43)



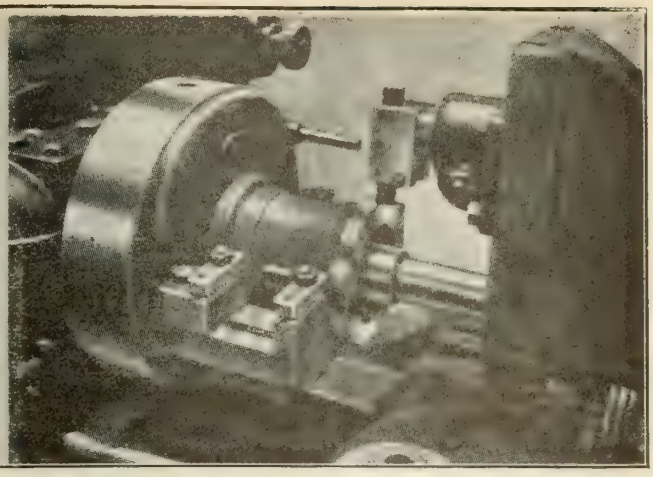


Fig. 2—View of work holding fixture before bearing is inserted. Fig. 3—Pair of half-bearings in jig for first operation.

Machine Work on Interchangeable Half-Bearings

Interesting Problem in Chucking—Special Clamping Lugs Cast on—Rear Face of Lug After Being Machined Acts as Locating Surface—Fixture Adjustable for Different Size Bearings

IN THE machining of bearing bushes cast in halves a variety of methods are employed, especially in the chucking, which presents an interesting problem. The object to be attained is, of course, the production of interchangeable bearings with the joint exactly on the centre line, combined with an easy and rapid method of chucking.

The most elementary method, quite commonly used, is to grip the half-bearings in a four-jaw chuck, after machining the joint. The half castings are kept together by a clip, the joint being set central with the aid of a scribing block. In some works it is the practice to dispense with the clip by sweating the two portions together for the machining process.

For some years the Alfred Herbert Co. have been using a method of chucking and machining half-bearings which has proved very successful both in their own practice and with other engineering firms using the same equipment. By this method it is necessary to make the rough castings in a special way with chucking lugs cast on; a detail is shown in Fig. 1. In this particular instance the centre lugs can be ignored, as they are part of the design of the bearing and are not essential to the method of handling. The lugs near the flange are those specially cast on and subsequently removed.

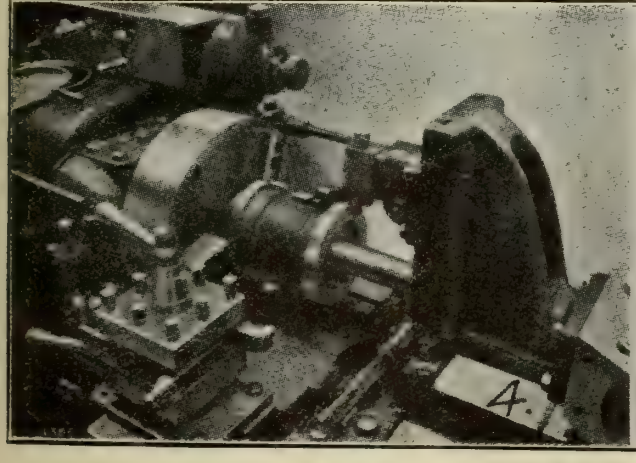
Previous to the lathe operation, the joint face on both halves is machined by grinding or milling. After this, a second operation on one half only consists of machining the opposite side of the lugs A to a pre-determined thickness, faces A serving as locating points for the half-bearing in the fixture.

Fig. 2 shows the fixture before insertion of the castings, together with the platforms or locating ledges on which the lugs rest and are clamped. Fig. 3 shows a pair of castings assembled in the fixture for the first lathe operation. It will be noticed that the machined lugs rest on the ledges which lie below the centre line of the lathe, an amount equal to the thickness of the machined lugs A, Fig. 1. The half-bearing with the unmachined lugs is laid on top, the clamps fixing the two halves securely together and to the fixture.

Referring again to Fig. 2, it will be noticed that the locating points on the fixture are adjustable in two directions to accommodate different sizes of bearings; for instance, the locating and clamping blocks are movable parallel to the axis of the lathe; the holders to which they are clamped are also movable inwards or outwards on the fixture proper.

At the first operation, shown in Fig. 3, the machining operation consists of boring, turning over the flange with a knee tool and facing, operations which are performed by standard tools. At the second operation, shown in Fig. 4, the Coventry chuck is used for gripping the semi-finished bearings on the flange turned at the first operation, the work being located true by a plug in the chuck

(Continued on page 24)



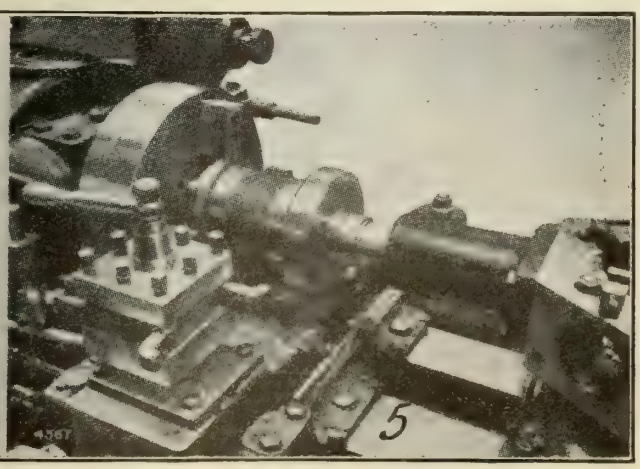


Fig. 4—Second operation on half-bearings. Fig. 5—Steady rest in position supporting end of bearing while lugs are turned off.

Operative Construction of Levers and Treadles

Outlining Various Designs to Meet Specific Requirements—Providing for Adjustment—Locating for Convenience of Operation Lever Operated Clamping Fixtures—Effect of Vibration

By FRANK H. MAYOH

FIG. 10 shows plan view of a lever operated tailstock for lathe used for quick operation of the tailstock spindle. This lever A is pivoted to the tailstock spindle at B and a slot in the lever engaging with a pin at C in a bar D completes this construction. By taking hold of the wooden handle E and pushing it in the direction of the arrow the lever is caused to assume the position shown by the dotted lines, while advancing the tailstock center F to the position shown by the dotted lines or in any intermediate position.

For Indexing Units

An important branch of lever construction has as one of their features incorporated therein what are known as indexing or locating units. These usually embody features common to standard lever design such as are shown in many of the examples illustrated herewith, while in addition a suitable pin arrangement is provided. The purpose of this pin is to locate the lever in a predetermined position. Two types of such levers are shown in Fig. 11, that in the upper view being of that type which are attached to the end of a shaft by means of a key to locate it radially, while a nut holds the lever in position. The lever itself is indicated as A, it being attached to the shaft at B, while in the boss C is a spring pin D, to the end of which is attached by means of a pin E a knob F, while a spring G completes the arrangement. In use an operator takes hold of knob F and pulls it back, thus compressing spring pin D until the reduced end is pulled out of a hole used for locating, after which the lever is swung radially about B as an axis until the spring D snaps into another locating hole, thus the lever and in consequence the mechanism operated thereby can be located at various positions, this being a construction similar to that employed on indexing centers. Another type of indexing lever for a similar purpose is often constructed with a ratchet arrangement.

In the lower view is shown a type of lever in which the same principle is embodied except that the spring pin operates at right angles to the indexing shaft. This is a convenient arrangement where the indexing is to be confined to a portion of a circle. Here the lever is indicated as H and integral therewith is machined a stem J, slidably mounted on this stem is a sleeve K. Attached to the outer end of this sleeve by means of a pin L is a springpin M. The sleeve K is knurled to give a good hand grip and in indexing the operator pulls back sleeve K thereby compressing spring P and pulling the spring pin M out of the hole N. The lever H is then moved to the next hole where the spring pin snaps into position, thereby locating the lever which in turn locates the shaft and attached mechanism (not shown) in the desired position.

Straightline Movement

A lever action used as a toggle for operating a straight line movement is shown by Fig. 12. Here the lever is curved under so that it may be connected with a foot treadle, and although it cannot be termed a hand lever it is used in common with a foot treadle and illustrates the principle of design which results in a very powerful action. The lever is indicated at A attached to the lower end of which is a connecting block B, which pivots on a stud at C in one direction and in the opposite direction on a stud D held in place with a nut. The lever A pivots about the stud E as a center, the upper end of the lever being made to form one-half of a toggle action. The other half of the toggle is provided for by a link F which pivots at G, while the link and the lever are connected with a stud at H, the entire arrangement being used for pushing the slide J in the direction indicated by the arrow with a powerful action, it being evident that the nearer the lever and toggle action come to being in a straight line the more powerful is the action. A spring is used on the operating foot treadle to return this mechanism to its starting position.

A group of rather simple lever constructions are shown in Fig. 13, each of which illustrates a principle which it is felt should be included in a discussion of this type although familiar to many. In the upper left hand corner is shown a plain off-set lever A, this having a handle at the upper end while it pivots at B, and at C it is connected to a rod which operates a clutch such as is shown in the upper right hand corner of this view. A foot treadle of the rocking type is shown to the right of this construction in Fig. 13. This operates in a manner different than any previously described as movement is imparted to a shaft indicated as D in a rotary manner, by stepping on either side E or side F of the treadle which imparts a rocking movement to the shaft, this in turn operates the mechanism attached there-

The first part of this article appeared in Nov. 2nd issue.

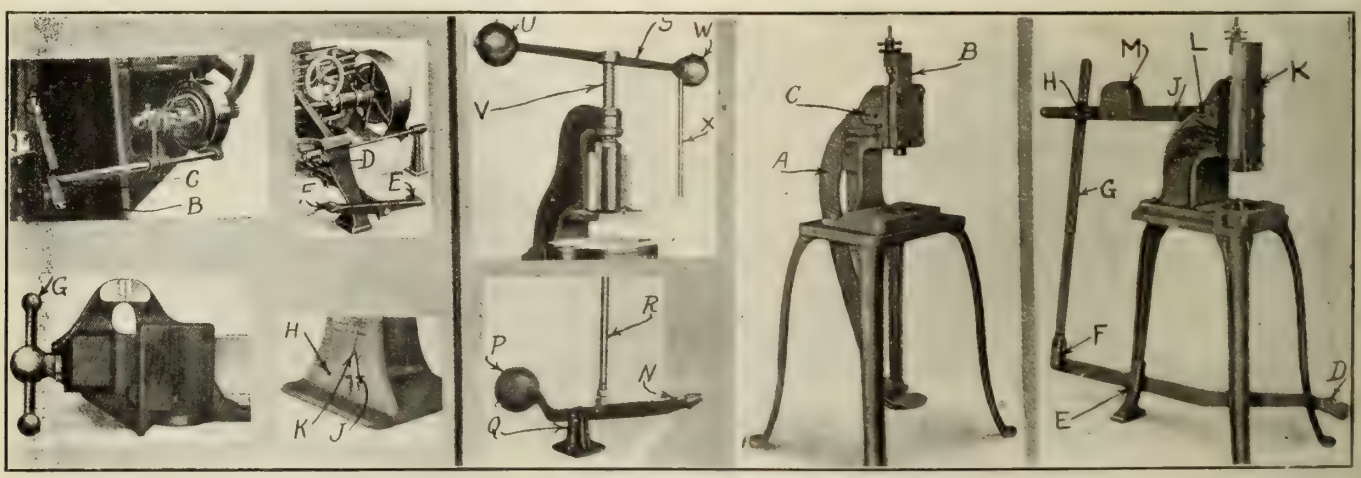

Fig. 13.—Two simple lever constructions and clutch operated press. Fig. 9.—Four lever examples of standard design.

to, which might be a clutch operating sleeve or other lever mechanism.

Bench Vise

Most everyone is familiar with common bench vise construction and it is therefore felt that no description is necessary with reference to the construction shown in the lower left hand corner of Fig. 13 except to say that bar G may be held by hand in the position shown for getting a two hand grip on it or it may be slid so that the ball at the end is in contact with the center portion of either end for a one hand grip, or to get a greater leverage with both hands. The balls on the end of this lever also act as counter-balancing weights to facilitate movement radially of this lever when tightening the screw. In the lower right hand corner is shown a foot treadle often used in punch press construction, the particular feature to be noted in connection with this lever H is that a swinging piece J is provided near the base to permit the press to continuously operate.

Clamping Fixture

When handling work on the bench or for many kinds of machine work where a rapid change from one length to another is desired a construction embodying the feature of operation shown in the illustration Fig. 14, can be often used to good advantage. In this illustration a section only of a tool is shown, this consists of a long strip A made of steel which is held to the bench by screws B. In the top of this strap are teeth of ratchet form which are caused to coact with the lever C shaped so as to form a handle with a pawl at its lower end. This is pivoted at D in a block E and the handle is so proportioned that the weight of it will be to the left of the center as shown, thus the pawl-handle will naturally engage the teeth of the bar A. Another unit of the fixture would be constructed at the opposite end of the bar A of a nature for handling the particular work used for; this end would be unadjustable except as necessary for handling one length of work. When changing from a long length to a short length an operator would simply take hold of the handle shown and slide the block along to the desired position for gripping that particular length of work, where the handle with pawl would engage a tooth in the bar and the work would be clamped against this slidable block.

Fixture for Squeezing

A toggle action lever construction used in a bench fixture for squeezing is shown by Fig. 15. Here the base of the fixture which is made of cast iron is indicated as A which is held by screws to the bench shown below, pivotally connected to the fixture at B is a lever C and this is in turn connected to two toggle levers D and E by a stud F, while the other ends of these toggle levers are attached by means of a stud G to the long lever H pivoted on a stud J. A steel block K held by screws to the base of the fixture is provided so that lever C may be caused to squeeze between the space indicated as L. A yoke M is attached by a stud at N to the long lever H while a rod P is attached to a foot treadle for operating this device. Other features are the spring Q held to the bench by hook R for pulling back the device after it has been caused to operate, and a collar S pinned in place to limit the up movement of lever H caused by the spring.

In using this device an operator pushes down the foot treadle attached to rod P which causes lever H to pivot about stud J as a center, operating links D and E with G as a center to push lever C towards block K, all of which is quite a powerful action for a foot operated device, as center G works through a long are to apply a slight movement at F. It should be noted that the action of lever C is not a straight line action but rather a swinging action which brings up parallel in the position shown which is the end of the action.

Locating Device

Figure 16 shows two constructions of mechanism, one of which is used for locating purposes while the other is used for a ratchet operating lever.

At the left of this illustration a lever is used for locating in combination with two keyways and this lever A is made of cold rolled steel. It pivots on a stud B which is held in a block C, this block being screwed in place in a boss D on the frame-work of the machine. In the particular construction shown the lever A has an extension end X which comes through a slot in the boss D. Mounted in the boss is a bushing E held in position by a collar F. To this bushing is keyed other mechanism and the object of this construction is that with end X of lever A in keyway G this lever holds bushing E so it will not turn radially, thus the mechanism attached there is secured against rotation. By pushing on lever A the end X is caused to disengage in the keyway of the bushing E thus allowing the bushing to revolve until the end X drops in another keyway. Two keyways only for locating are shown in this illustration although more could of course be used.

Ratchet Levers

To the right of Fig. 16 a lever H is made to straddle a ratchet J, this ratchet being keyed to a bushing K which has a square hole in it to fit over a square shaft. A spring pin L having its end shaped to engage with a ratchet J is backed up by a spring M, thus an operator can push the lever radially in the direction of the arrow, which in turn revolves the shaft on which the squared bushing is mounted through the medium of the ratchet, while in pulling back the lever the spring pin L will ride over the ratchet teeth; thus an oscillating movement of the lever imparts a rotary movement to the square

bushing K, the squared shaft and the mechanism which it operates.

A description of this nature would be incomplete without reference being made to eccentric operating levers, therefore Fig. 17 shows two types of the same which it is thought will be suggestive of constructions along this line. In the upper view of this illustration the lever A is made in part with a shank B, which is reduced making a shoulder at each side which fits in a capped bearing C. At the end of this lever is an excentric portion D which enters a slot in (say for instance) a tooth clutch E. To operate this clutch the lever A would be revolved in either direction, thus the excentric portion of the lever D would move clutch E slightly up and down. This construction could be used in a toothed clutch, gear shift or for other similar purposes, it also being applicable to use with a friction clutch.

Eccentrically Operated

The construction in the lower portion of this illustration shows a lever G which has two eccentric slots cut in it on a radius H and J, entering these slots ordinarily would be pins mounted in sliding members, thus when the lever G is resolved about hole K as a center the pins would be caused to move inwardly or outwardly from the center of the lever, thus operating slides attached thereto. This construction is used on many split nut mechanisms for engaging a screw, one particular purpose in mind being that of operating the nut on a screw threading lathe.

A belt shifting lever is illustrated in the left hand portion of Fig. 18, here a long lever A is made of wood, this is pivotally connected to a block C held to the ceiling above the counter shaft. This lever is attached at E to a bracket D mounted on a rod F, the opposite end of which is equipped with forks for shifting the belt. In operation a pull on lever A moves it to the position shown by the dotted lines or a distance equal to B operating about G as a center. It is obvious that in doing this the center distance H is lengthened slightly through this circular action which is compensated for by the flexibility or play of the long members used in the make up of this construction, or by a slight swing backwards or forwards, this action being hardly perceptible in most cases. At the right of Fig. 18 the lever J pivotting about K as a center operates a sliding member L through the medium of a rocking lever P. This moves sliding member L a distance equal to Q, an elongated slot in its lower end, which engages with pin R, causes lever P to operate with a circular action on radius S, it of course being necessary to have a floating action on account of the change in the relative centers of the two levers where they engage with pin R.

For Grinding Machines

A rather elaborate lever construction is shown in conclusion, this being a construction common to grinding machine operation. Fig. 19 illustrating the same. Mounted on the grinding machine is a lever C which operates through an arc X on a radius equal to M. This action X is reduced to a smaller action through the leverage of N to M; the end N is connected to a rod D which is shown broken apart. The upper end of this rod D connects to a lever E which moves through an arc equal to P. This lever E is attached to F which is in turn attached to that portion of the counter shaft G. The lever E operates about H as a center and moves sleeve J to a distance equal to A, which in turn operates rod K thereby moving arm L to the position shown by the dotted lines. This causes sleeve B to operate clutch S, a portion only of which is shown.

This sleeve B moves a distance equal to T and it will be seen that an operator moving C at a handy position on the machine controls its operation by the interposed arrangement of levers and connection, all of which is in line with the principle of getting the lever where it is most apt to save time and labor of the operator even though it may require a few additional parts in the construction of the various units. In some types of machinery and more particularly in that class which are known as light high speed mechanism, where there is considerable vibration due to the rapid movement of parts a number of connections in the operative levers might be objectionable owing partly to the vibration induced by a large number of joints.

MACHINING HALF BEARINGS

(Continued from page 21)

which fits the bore in the bearing. As the front portion of the bearing might tend to spring apart under cut, the halves are securely clamped together by C-shaped clasps which grip on the lugs At the commencement of the second lathe operation, the second flange is turned, faced, and chamfered with standard tools, as shown. As soon as the flange has been turned, the revolving steady shown in Fig. 5 is brought up on the turret and locked against the chamfer on the flange, which thus securely keeps the two parts together This enables the C clamps to be removed from the lugs, so that the portion in between the flanges can be turned with tools in the square turret; this turning operation also removes the lugs.

Fig. 1—Half-bearing with special lugs AA cast on.

It will be appreciated that by this method of handling chucking is quite simple, and interchangeable work can readily be produced. This method has been applied with slight modifications to the machining of bearings lined with white metal, an additional operation being required, as two borings are necessary. Throughout the operations the work is always securely held, enabling high speeds and coarse feeds to be used, with a consequent high rate of output.

?? Questions and Answers ??

QUESTION: — What information have you with reference to Canadian trade with India? Has there been any remarkable improvement recently and what lines seem to be in demand?—J. C., Windsor.

Answer:—Department of Trade and Commerce reports that Canadian goods to the value of $350,000 were imported by India during the three months, April to June, or over three times more than the same period last year, when 80 per cent. of the trade represented a certain make of motor car. This year, however, only 50 per cent. of the three months' total represented motor cars of all makes. Thus, Canadian goods in much greater variety are now reaching India. About 34 per cent. of the motor cars now going to India are from Canada. Customs tariff, recently increased from 20 to 30 per cent., favors the light, inexpensive car as made in Canada. While industries of all kinds have been encouraged in Indian provinces of recent years, it is reported that difficulty of securing efficient labor has been a serious handicap. It is said that a total of over 30 million dollars was invested in Bengal province alone. The ventures consisted of tanneries, boot and shoe factories, soap factories, rubber and glass factories, metal, machinery and chemical plants, but it is said that practically none of them have fulfilled the expectations of promoters. Naturally, failure to produce economically in certain lines, will broaden the market in these goods for the exporter in other countries.

* * * *

Question:—What are the prospects of further reductions in the price of pig iron? You are now quoting $36.30. Will it drop to $30 by the New Year?—T. L. M., Toronto.

Answer:—It seems safe to say that a decline of $6 within the next six weeks is somewhat out of the question. Canadian furnaces are operating on restricted capacity. They claim that difficulties in securing materials are such that pig iron business is somewhat unattractive. The U. S. market is hovering around the $30 level, and at that there is very little market though it is improving. There are those who predict that pig will drop below $25 across the line before Xmas. Foundries are buying from hand to mouth. A decline of $2 50 a ton in Canadian iron is announced. This is a sympathetic drop to meet Buffalo prices. British pig iron is a factor in the East, but, it is said, will pass out of the market with more normal Canadian output.

* * * *

Question: — We frequently have trouble in pouring babbitt. Is there any method whereby uniform run may be ensured?—J. R. T., Brantford.

Answer:—It is claimed that a small piece of rosin, about one-inch square, placed in the metal, will give the desired result. It is necessary, after stirring and mixing thoroughly, to remove the scum. When boxes are fogged, or damp, it is said that such a mixture is a safeguard against blowing. Babbitt will sometimes pour well in one place, but only poorly in another. The use of rosin, it is said, gives desirable uniformity.

Canadian Machinery and Manufacturing News would have its readers feel that its resources for gathering special information, such as they may require, are freely at their service. Their questions will receive immediate consideration. On the other hand, should they feel that they are in a position to add to the information given in these columns upon any subject, their co-operation will be greatly appreciated. Desired information is first sent by mail to enquirers. Names will be supplied upon request.

WOULD DEVELOP EXPORT LINES

Question:—Can you advise us of any line that might be produced in Canada upon which an assured export business could be built up? While we are not fully equipped at present, we feel that Canada's industrial future will be directed largely toward export lines. It is a question upon which we need fullest information. What is there in iron and steel that could be developed as an export specialty?—R. A. C., Ottawa.

Answer:—Unfortunately this is a rather general question and we would suggest that the inquirer get in touch with the Commercial Intelligence Service Department of Trade and Commerce. The competitive factor is a strong one, but cases are known where Canadian specialties have been marketed abroad with great success. It is in this department, apart from staple lines of merit, that export business seems to promise most. In this connection, it cannot be out of place to reproduce a letter written to a representative of Canadian Machinery by C. H. Withers, export manager for Robert Grant, Ltd., iron and steel suppliers of British, American and Continental materials, 62 Bath St., Glasgow, Scotland. The writer states:

"I have recently been discussing with my directors, the possibilities of using the Dominion as a source of supply, and on the assumption that you will be interested in helping to 'boost' up Canada's trade, I am taking the liberty of approaching you to ascertain whether you can advise me of any likely firms who would be interested in exporting their materials to various parts of the world.

"I might mention that we are not so much interested in dealing with the bigger and better known concerns, but rather the smaller type of mill who would be in a position to offer us competitive prices, and who would be interested in forming an alliance with us with a view to building up an outlet for their material. I might mention that through our attachment with the smaller mills here and on the continent we have built up for them a considerable amount of business.

"The class of material in which we are most interested in purchasing in Canada would be as follows: —Semi-finished products, billets, slabs, wire nails, wire rods, ordinary and barbed wire, tank, ship and boiler plates; black, galvanized and corrugated sheets, tubes of all descriptions.

"While I am quite aware that Canadian prices may not prove competitive at the moment, we feel convinced here that the time will come when Canada will be in an excellent position to quote in competition with the United States, and we are therefore anxious to obtain connections now so that we shall be prepared when business conditions become more established. We feel sure that the time will come when American material (in the general sense) will become highly competitive in the overseas trade.

"A further strong point in our organization lies in the fact that with regard to interchange of communications we have our own special code by which detailed specifications, enquiries and quotations may be sent by cable at a very nominal expenditure, and in most instances by the use of not more than two or three words.

"I have taken the liberty of writing you fully on this matter, knowing as I do your great interest in assisting firms in Canada to enlarge the growth of their business, as I feel that if we could get in touch with them very good business may result in the future. Of course, this may be a matter of even a year

(Continued on page 48)

Many Tinkers, Too Few Experts, Says Judge Gary

Those Who Talk Loudest About Economic Matters Sometimes Know the Least—Elements of Thrift and Prosperity Discussed —Value of Publicity Not Fully Appraised—Supply and Demand

DISCUSSING problems of supply and demand, the absolute futility of any man-directed effort that did not observe carefully the law of cause and effect, Judge Elbert H. Gary, chairman of the United States Steel Corporation and president of the Canadian Steel Corporation, whose plant is now being built at Ojibway, Ont., emphasized the point that private or personal gain or advancement or political advantage must be subordinated to the general public good.

"In the consideration of all economic questions," said Judge Gary, addressing the American Steel Institute, "everyone should endeavor to determine the final effect upon the people as a whole. Personal or private gain or advancement or political advantage must be subordinated to the general public good.

"Our business life is represented by various groups of men and women and involves a great diversity of economic activities. Taken alone, each branch of industry is naturally selfish and influenced more or less by unworthy motives. In discussing any particular one, all others must be considered as a part of the general public. If in management any wrong or injustice is perpetrated, it is the general public which must finally in some way suffer the consequences.

"As industry has developed, populations multiplied and wealth increased, the problems and difficulties in economic life have grown and we have been correspondingly forced to concentrate our minds upon proposed measures for relief or protection against imposition.

"We are still suffering from the very high cost of living caused by the inevitable cycle, developed during the war, which carries high prices from a starting point in a given place, proceeds around a spiral and returns step by step to a higher basis. Speaking generally and yet making the illustration specific, labor, which constitutes eighty-five per cent of the cost of production, is paid very large rates, but, with exceptions is not paid more than is proper, because compelled to pay high prices for the living costs. Normal conditions have not been fully restored and apparently are not likely to be in the immediate future, unless extraordinary efforts shall be made.

"We are apt to conclude that everything objectionable can be overcome by the adoption, amendment or repeal of laws. But on reflection one possessed with average intelligence and information, knows this is a fallacy. Many laws have been passed which are improper, and no doubt new ones ought to be enacted, all bearing upon economic questions. This will always be the case.

An Inexorable Law

"It is the purpose at this time to refer briefly to certain old and fundamental principles, which in modern times have been by large numbers overlooked or at least underestimated. Reference is made to the law of supply and demand.

"This law is inexorable. It is like the mills of the gods. It may be slow but its work is sure and fine. In its

JUDGE ELBERT GARY,
Chairman, U. S. Steel Corporation.

application, it is technically the doctrine expressed by the old and well-known phrase "quid pro quo." Individuals, groups, populations, become habituated to the idea that it is possible and also justifiable to get something for nothing; to get it by flattery, by mere promise, or by main strength and physical force.

"But it might as well be admitted first as last by every individual, collection of persons, or nation, that in order to obtain what is desired, there must be rendered an equivalent value, and that if secured on any other basis the business will not be satisfactory. What amounts to an equivalent or fair consideration in any transaction is, of course, mutually determined by the parties concerned, and if each agrees freely and voluntarily with full knowledge of the facts, uninfluenced by coercion, action is and should be final.

"What is to be done to prevent a practice which increases prices or costs from a starting point around or across back to the start and again commences another advancement? The first thing for every one of us to do is to think. One of our most prominent and ablest editors not infrequently urges us with emphasis to think, earnestly, seriously and all the time. We must adopt and practise the suggestion.

Must Not Be Interfered With

"When we ponder over the situation with the idea of suggesting a remedy, the first question presented relates to combinations or conspiracies to suppress natural laws. If one is actuated by motives of cupidity or dishonesty one is apt to suppress and then oppress. A combination calculated to control business or production either as to quantities or prices, by the employers or by the employees, interferes with the natural course of business and results in hardship upon all who are outside of the combination, who may be termed the consumers. A moment's reflection will bring conviction that it is because of these conditions, legislation has been invoked with the ostensible purpose of protecting the public, though it must be admitted that sometimes the real motives have been quite contrary to this idea.

"From what has already been said you are probably at least mentally inquiring, what is to be done? What is now proposed? How can business be done with fairness and with justice, except by the adoption and enforcement of laws which absolutely control business as to prices, rates, deliveries and all other particulars, and which secure proper treatment to every one, even though this would necessarily interfere with full, free and unlimited action on the part of all different groups in the advancement of their own interests respectively?

"Every one should attempt to answer these questions for himself or herself. A proper answer would be that the natural law of supply and demand should not be interfered with by the Government or by any administrators of the laws, except in case of turpitude, and

this applies to all business transactions. There are already too many man-made laws, and perhaps too many attempts to apply them, which are calculated to interrupt and hinder progress and industrial prosperity.

"The utilization of the great wealth, natural resources and productive capacity of this country should be permitted without interruption or hindrance up to the limit of propriety. But how shall this be accomplished since laws and their enforcement provide the only absolute rule for the conduct of persons? The answer is, by the enforcement of all those laws which establish order and safety of person and property as against riot, physical force and intimidation; enactments or amendments which permit immigration of foreigners on the basis of quality rather than numbers; and new laws or amendments which permit and require full publicity

"If one seeks to acquire property of any kind, or service, a fair price must be paid; or if service demands a certain price, the fair equivalent in work should be rendered. Any attempt to bring about rules of conduct contrary to these fundamental principles will not be successful. If put in practice by force or fraud they will eventually fail. There must be standards that are just and logical, as between the parties connected, and not inimical to the public weal.

"When an individual or association of individuals can and does collect an unconscionable amount for a commodity or for work, as the result of any circumstances or combination, the general public must and does finally pay the bill. This is inevitable and it is a pity that large portions of the public overlook or ignore this fact. It is not difficult nor embarrassing for a man in business to increase the production cost of what he sells by additions in salaries or wage rates if, at the same time, he correspondingly increases selling prices."

of economic transactions so far as they affect the public welfare.

Value of Publicity

"We have not fully appraised the value of publicity. Its practical results and its necessities in all departments of economic life without discrimination or exception have not been given due consideration. The full exposure to the people of business methods and management on the part of public and private institutions and organizations will create and firmly establish a powerful, effective and satisfactory public sentiment, which, on the average and for the long run, will be more potential than penal statutes.

"There is nothing to be said at this time against labor organizations or their leaders; certainly there is or should be no personal animosity. But to permit any group, and this representing only a minority in its branch of industry, to be exempted from publicity, is an injustice and a wrong to the general public.

"It goes without question that in business there are numerous matters relating to operation and management which are of interest only to the persons or concern connected, and these need not and should not be divulged to the general public, some of them particularly before consummation or pending negotiations; but as to the matters which at the time affect the public welfare there should be the right to have inspection by a competent, disinterested and non-partisan body. Let us demand in this country full, fair, impartial, competent publicity, applied without fear, favor or discrimination.

World Needs Economy

"The steel industry should and would welcome such a condition. It was proved to be desirable and proper during the panic of 1907 and a short period succeeding. There is no good reason why the public, through proper agencies, should not be present at private meetings of groups. It is, however, wrong to treat any branch of industry differently from all others. Of especial interest just now is the treatment, with like rules, privileges and penalties of both employers and employees. Unless and until that is brought about there can never be industrial peace nor can the public interest be protected. The untrammeled right to contract and the right to enforce contracts, both based on the law of supply and demand, together with opportunity on the part of the public to have the facts exposed, are essential to the protection of the public interest. Partial, prejudiced or incompetent investigations will not suffice.

"The fault or lack of continual prosperity in a measure may be laid at our own doors. If so, then let us to the best of our ability overcome our faults and consistently adopt and practise reasonable and constructive policies.

"Fault in many places no doubt exists. There are too many tinkers, too few experts. Many individuals, by reason of political position or other limited success, assume to know a good deal about matters, particularly economic, concerning which they have little information, derived either from study or experience, and these generally talk the loudest and longest on these subjects. Others from a desire to control or create antagonisms or to derive personal profit, attempt to interfere with the natural and reasonable course of business, sometimes resorting to force and brutality. We must keep our own houses clean, search our own hearts, remain true and loyal and above reproach, and then openly proclaim the truth at proper times and places.

"The world, now more than ever before, needs peace, international and domestic, political, social and industrial. It is a time for work, economy, saving, thrift; honest, reasonable and intelligent recognition, observance and enforcement of the rules of law, propriety and common sense. Gentlemen, what we preach let us practise, conscientiously, persistently and loyally. Let us always transact our business on the basis of rendering a full equivalent for what we demand or receive. Thus we shall best succeed and prosper.

Condition of Steel Business

"There are no obstacles to continued prosperity in the iron and steel business of the United States except such as may arise from interference with the natural course of supply and demand. There is a great abundance of high quality iron ore; steam, gas and coking coal; limestone and other raw products, all within easy reach; also furnaces, mills and shops of higher grades, railroads and ships for transportation, every variety of experts of pronounced ability, organizations and systems equal to any in the world; and the demand for every

"In spite of the difficulties which have confronted industry and appreciably frightened investors, the manufacturers of steel are now producing, on the average, about seventy-five per cent. of their estimated capacity. This is more than double the total capacity twenty years ago. We are making a better quality of steel, and increasing diversification of shapes for additional uses; and in many ways we are extending capacity and effecting economies, although selling prices have not kept pace with larger costs. We shall soon get back to a basis of business that will yield fair profits, if permitted to proceed without unreasonable interference.

"As to the general business conditions, in addition to what has already been said, great significance should be given to the publications concerning the enormous savings bank balances. These show conclusively a disposition to economize, whatever may be the reasons. Economy and saving are fundamental to thrift and prosperity."

kind and character of steel is far in excess of capacity to produce. Steel is needed immediately for buildings and structures, for railroads, for farms, for pipe lines, for canning, for equipment of every kind, for guns, tools and implements of thousands of varieties, for wire, ranging from the finest watch springs and piano strings to the largest cables, for cars, automobiles, aeroplanes and other vehicles for transportation of property and persons, and many other purposes.

"If the natural course of business had not been interrupted we would now be enjoying success and prosperity in our industry greater than ever before, so far as volume is concerned. Who is blamable? The answer is: Any one who by word or deed has interrupted or hindered the operation of the natural law of supply and demand; or has interfered with the full, free and unlimited right to work, to operate and produce.

Practice on Quenching Mediums for Hardening

Oil Gives the Best Proportions Between Hardness, Toughness and Warpage—Care Should be Taken to Keep Water Out of the Bath—Brine and Acid for Extreme Hardness

THE MOST common of the quenching mediums in every day use are water and oil. Some concerns use brine and acid solutions. Others use alkali solutions. The reasons for different mediums are the requirements of hardness, warpage and toughness.

The alkali solutions cool the steel through the critical range or from hardening temperature to the black stage at a slow rate. The hardness of steel depends upon this rate. In consequence, the use of alkaline solutions gives the least amount of hardness possible when quenching in a liquid to the cold stage. The loss of hardness is compensated for by the toughness and by great elimination of the warpage tendency. The grip received by the hot steel when plunged into the bath is so lessened that the case of the steel does not set with such hardness that the strains, etc., in the main bulk cannot bend it to a position of strain equilibrium. The alkali quench is adaptable to treating steel such as axles, etc., for certain desired physical properties. For carburized work the alkali solutions are well adapted for quenching for core refinement on delicate parts that would warp excessively if quenched in a faster medium. The alkali solutions are not generally used for the reason that with different grades of our standard steels, stock may be so selected as to give the desired physical results with the more universal oil or water quench. However, for obtaining certain physical properties which the steel does not have with oil or water quench, the alkali solutions are adaptable. The alkali solutions are made with lye, soda ash, soap, etc., and to various strengths, according to the final results desired.

Oil cools the steel at a faster rate than the alkali solutions. Oil is the most all round quenching medium used. For our standard steels, the oil quench gives the best proportions between hardness, toughness and warpage.

In the past such oils as fish, linseed, etc., were considered as the only oil in which steel could be quenched. This belief was handed down from the time when these products were low in cost. At present the cost is excessive and when one considers the odor of fish oil and the accumulation of gum about the top of the quenching tank from cottonseed, one wonders why such oils retained their popularity as long as they did. The only advantage which these oils possess is the high flash point.

These oils, however, were largely supplanted prior to the war by special compounded oils of the soluble type. The soluble properties consist of the ability of the oil to make an emulsion with water. There is a slight advantage to this in that if water gets into the oil it combines with it to form a medium which is slightly faster for quenching than the oil itself. Further, the medium is uniform in its properties throughout the whole. On the other hand, if the water did not go into emulsion, it would separate in the bottom of the quenching tank and the hot steel, passing through the oil to the water, would receive unequal hardening strains which would have a great tendency to crack the work. There should, however, be no reason for getting water in the oil in a well-designed plant. The soluble oils are further advertised to quench greater quantities of steel per gallon of oil and to have high refrigerating qualities. The ability of any oil to quench large quantities of steel per gallon of oil depends on how fluid it is or its viscosity or draining qualities. The lighter the body of the oil the better it drains from the work. The so-called refrigerating qualities are no more than the oil's ability to remove the heat from the steel at a fast rate and then radiate the heat it carries to the atmosphere, the amount of heat carried per unit of oil is the specific heat of the oil. These properties are further improved by a light-bodied oil that will circulate itself by thermo-syphon effect.

Further claims are made that the physical properties of the quenched steel do not vary to an appreciable degree when the oil is used up to temperature of 200 deg. to 250 deg. F. These claims are in the main true, but are in the main true of other oils. There is very little sense in the usual shop of allowing the oil to go to such temperature. The discomfort to the men through burns, etc., is great.

Other than the above properties which these oils are claimed to possess there is perhaps no advantage over any other oil as far as the hardening of the work is concerned. A good quenching oil should possess a flash and fire point sufficiently high to be safe under the conditions used. 350 deg. flash point should be about the minimum.

Viscosity should be sufficiently low to allow the oil to drain from the work readily and circulate itself freely by thermo-syphon action. Average of oils run about 115 deg. to 150 deg. at 100 deg. F. and 150 deg. Saybolt is recommended as a maximum.

Specific heat regulates the hardness and toughness of the quenched steel. The higher the specific heat the harder the steel. Viscosity must also be considered to some extent. Specific heats of quenching oils vary from .20 to .75, water considered as unity. A specific heat from .20 to .40 is usually found with the fish, animal and vegetable oils, from .50 to .70 with the soluble type and mineral oils. Further, the oil should contain no water, should not gum on use and should not be of disagreeable odor or become rancid and should have no skin-drying effect on men's bodies.

A great many concerns are using paraffin mineral oils for quenching, and a few are using crude fuel oils.

The following is a résumé of a recent test on various oils:

The method of test was to heat up to a temperature of 1,400 deg. F. a cylinder of steel weighing 3510 grams. This block was heated in a lead pot maintained at 1500 deg. F. Ten liters of each oil under test were used. A thermocouple was placed in the center of steel cylinder for accurate readings of the cylinder temperature at all times. The temperature of the oil was taken with a thermometer, before and after quenching the cylinder. The number of seconds required to cool the steel from 1400 deg. F. to 800 deg. F. and from 1400 deg. F. to 500 deg. F. was also taken. This data gave a comparative specific heat value by the formula:

$$C = \frac{c\,w\,(t - T')}{W\,(T' - T)}$$

where c w and t are specific heat, weight and original temperature of piece of metal quenched; and C W and T are specific heat, weight and original temperature of bath of oil in which it is cooled, and T' is the final temperature of both. For the test c equals .1165, w equals 3510 grams, and t equals 1400 deg. F.

Mixtures of oil and water are used in a few instances in different proportions, to give a greater hardness than the straight oil and a less hardness than water. This can only be done with the soluble type oils or such oils as will emulsify and make the usual milky solution with water. The following experience shows one instance where such a solution was used:

A concern making permanent magneto magnets were experiencing trouble in cracking and warping when the magnets were water quenched. On the other hand an oil quench, though causing no such trouble, did not give the desired hardness for the magnetic requirement. A quenching bath of three parts water to one part oil was mixed and satisfactory results were attained, which help-

As recommended by the American Gear Manufacturers' Association.

ed them out of the immediate trouble until such a time as the steel and the fabrication of it was rectified.

Water is the most used of the quenching mediums and its cost is very little. Its use is primarily only restricted from its action of warping delicate work. The colder the water the harder the work. Water at boiling point, 212 deg. F., is supposed to have the quenching properties of oil. Addition of alkali which raise the boiling point will undoubtedly give some such results. The cost of alkali and the cost of maintaining the water at a fairly constant heat in combination with uncertainties are oftentimes more expensive than the use of oil as a quenching medium. Water, however, is as a rule plentiful and no pump or cooling devices are necessary as with oil.

Brine and acid baths are used where extremely hard work is desired. The quench is very rapid. Great warpage results and likewise cracking of the work. Many hardeners have devised fast quenching baths, the secret of which they carefully guard. These sometimes have merit for particular classes of work but for our standard steels there is very little use for them.

There are a few other methods of quenching, which, however, have no great value for carburized work.

By quenching in molten metals, such as lead, the hardness is decreased as the steel cools from the red to the black stage at a slower rate and the work is tempered to the temperature of the lead. By quenching in mercury extreme hardness is assured. This is only practical on very small parts desired extremely hard.

Keeping the quenching bath cool is important when using solution or oil. There are three ways in which this is accomplished: first, using a large quantity of the liquid; second, circulating the oil past colder objects; third, passing colder liquids in pipes through the oil.

In using large quantities of oil, the oil will retain approximately its surrounding temperature if there is one gallon of oil for every pound of steel quenched per hour, circulation of oil past steel to be one gallon per hour. One concern has a circulating supply of oil of 3,300 gallons which will normally be 70 deg. F. on a Monday morning; 12,000 pounds of steel are quenched. The oil temperature at the end of the week is 120 deg. F. The pound hour rate of steel is 219 pounds per hour. The rate of oil flow is sixty-four gallons per hour. Increasing the oil supply would keep the temperature of the oil down at the end of the week, though the temperature of 120 deg. does not cause trouble with hardening.

In circulating the oil past colder objects the oil is pumped from the quenching tank through pipe to the cooler. The cooler may be a brine tank cooled by an ammonia refrigerating system. It may be a reversed water heater where the oil passes through many lengths of piping and cold water flows about these. It may be metal sheets set at angles on which the oil is sprayed and allowed to flow from one to the other (a downward, zig-zag motion) and collected and pumped back to the quenching tank. It may be an open tank in which half the periphery of many revolving discs are placed and air blown past the exposed disc which has the oil film. Any of these methods is good practice. Spraying in the open air after the style of the cooling ponds of steam plants is not used because there is no evaporation and therefore no cooling from the latent heat of evaporation, and, due to wastage, this method is not recommended.

Engine Oil	190.9	96	.4120

	Condition of Oil when Held at 240 deg. F. for 60 Hours.
Fish Oil	Thickened and lump, very bad.
Raw Linseed Oil	Dark and thick as a light grease.
Mineral Oil	Dark and thickened considerably.
Mineral Oil No. 1	Dark a little and some deposits, thickening.
Mineral Hardening Oil	Dark a little and some deposits, thickening.
Soluble Type Oil	Dark with heavy sediment deposit, thickening.
Engine Oil	Very dark, thick and lumpy.

In passing colder liquids in pipes through the oil, the oil itself is not circulated. Water pipes are laid in bottom or at sides of tank and the cold water passed through. Cold brine from an ammonia refrigerating system is used for large installations, desiring low temperatures.

MAKING BELTS ENDLESS

Where endless belts are to be used the work should be done by the manufacturer in his own factory if possible. This operation is one for experts. Some manufacturers send expert belt makers out to make belts endless where belts cannot conveniently be sent to the factory.

A good general purpose joint is the cemented splice. But it entails a lengthy operation. The length of the splice for leather belts is an open question. The following conservative rule will be safe under all conditions where the belt splice should be 10 inches; from 10 to 18 inches it should be equal to the width of the belt, and above 18 inches a uniform splice of 18 inches will answer requirements. The belt glue should be applied hot and the belt allowed to stand in the clamps for at least 2 to 4 hours. Glue may be made waterproof by adding a small amount of bichromate of potash a short time before applying.

Canvas, rubber, balata and some solid woven belts are joined by a step splice in which the plies are cut away and overlapped. They are first cemented in place and then stitched to give added strength. The joint should be still further reinforced by a covering of heavy duck cemented in place. Rivets are sometimes used for additional reinforcement. The cement joint while efficient takes considerable time and special tools. Although in some transmission, an endless belt is a practical necessity, ordinarily steel lacing is found preferable, considering the relative expenditures of time, labor and money involved. This is not merely the statement of the manufacturers—it is the findings of many good belt manufacturers and engineers the world over.

Never try to put a belt on or take it off moving pulleys with bare hands. This is a good rule to follow if absolute safety from injury is to be had. In cases where pulleys are revolving even at slow speed, use a stick or belt shifter. Keep hands and arms away from the belt entirely. Where cone pulleys are used a belt shifter placed where a workman can reach it without moving will materially increase the production of that particular machine unit. Efficient belt shifters also tend to decrease insurance requirements and greatly lengthens the life of a belt.

In placing a belt on the pulleys do not have it too tight as it may be injured in forcing it on. When the belt is first put on insert, say a 6-inch strip of the same material as the belt, if that is the estimated amount of stretch, using lacing for making the joint. When the first sag is observed, take out the 6-inch strip and insert a 5-inch strip. As the belt stretches, reduce the size of the inserts until the belt rests under normal tension. Another method is to trim an inch at a time from one end of the belt as it stretches until the final length is reached.—From Short Cuts to Power Transmission.

News From the Welding Field

Result of Several Tests Made on Welded Cylinders

Method of Making Seamless Pipe—Process of Welding Girth Seams—Practice Followed in Testing the Welds—Results of Observations—Determining the Factor of Safety

By PROF. E. A. FESSENDEN and S. J. BRADFORD

THE following observations were made during the test at the pressure indicated:

1,000 lb. per sq. in. Scale began to crack at bend of flange in head at end of section 1.

1,200 lb. per sq. in. Distortion of head at end of section 1 continued; head at end of section 6 began to show distortion.

1,400 lb. per sq. in. Considerable distortion apparent in both heads. The head at the end of section 1 showed an increase in diameter in the part flanged over into cylindrical shape as indicated in Fig. 10.

1,700 lb. per sq. in. Complete failure occurred suddenly by tearing the acetylene-welded longitudinal seam. Failure apparently began by the material which had been added from the welding wire tearing away from the plate for a distance of about 3 in. Then the tear extended in both directions through the body of the weld itself until total length of the tear was about 16 in. The broken surface exhibited a very coarse granular structure. Fig. 11 shows the final fracture. The part which is thought to have failed first is below and to the right of figure 2 in the photograph. Where the tear left the weld and extended into the shell material at the left-hand end is also shown.

Fig. 11—Final failure of acetylene-welded longitudinal seam of cyl. No. 4.

Extract of a paper presented at a recent meeting of the American Society of Mechanical Engineers. The first part appeared in the October 19th issue, the second in November 2.

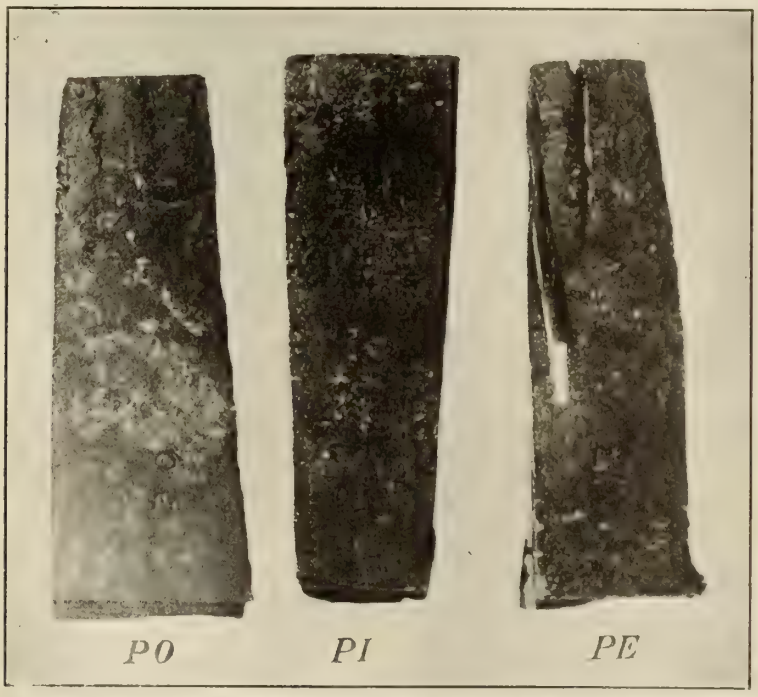

Fig. 12—Cracks in specimens of cylinder No. 1 revealed by etching and the crack in piece P E which probably caused failure.

The factor of safety, computed on the same basis for cylinder No. 1, may be taken as one of the following figures: (a) On the basis of the first noticeable distortion of the cylinder head, the factor is 5.41. (b) On the basis of final complete failure, the factor of safety is 9.18.

For the pressure at which the acetylene-welded longitudinal seam failed and assuming the effective thickness of the weld to be the same as that of the shell material, the stress in the seam was 40,500 lb. per sq. in. Measurements on samples of the weld cut out for tests showed the average actual thickness of the weld to be 0.358 in., so that the actual strength of the weld was 28,300 lb. per sq. in., or 10,140 lb. per linear inch of welded seam. Three samples were cut from the longitudinal seam at a point well removed from the section which failed and subjected to tension

5 (acetylene-welded)	....	5715[1]	.....

[1] Stresses marked thus are simply the highest stresses reached in tests where the final failure was due to other causes than failure of the seam in question.

tests by Professor Patterson. The results are given in Table 4.

The average ultimate strength is above the requirement of the Boiler Code of The American Society of Mechanical Engineers for good forge welds. The fractures exhibited the same characteristics as were described for the test pieces of cylinder No. 1, except that one specimen, sample L, failed by pulling the welded-in material away from the shell material instead of tearing through the centre of the weld. The other two specimens showed a discolored region in the fracture that indicated the same poor knitting together at the bottom of the scarf already commented upon in the description of the fractures of weld specimens in connection with cylinder No. 1. The average ultimate strength of the acetylene-welded seam per linear inch of seam computed from Professor Patterson's tests, is 10,770 lb.

Test On Cylinder No. 5

The shell of this cylinder was made of seamless pipe 12¾ in. outside diameter, with pressed dished heads acetylene welded to the shell with the convex face outward, the construction being the same as that of cylinder No. 2, except that the finished cylinder was only about 3 ft. long instead of 6 ft. A short time before finishing the tests on the first four cylinders already described, it was decided to test an additional cylinder taken out of stock. Therefore, cylinder No. 5 was chosen from a pile in the welding shop. One of the welded girth seams did not appear to be as good as those in some of the other cylinders, a second course of welding apparently having been run around the seam.

As this cylinder was tested simply as a check to compare the workmanship on stock cylinders with those submitted for test, it was not considered necessary to take detailed observations during the test. The cylinder behaved in practically the same manner as cylinder No. 2 except that no leakage through the circumferential seams was observed. Final failure occurred at a pressure of 1,900 lb. per sq. in. by serious leakage through an acetylene weld securing a pipe coupling in one of the heads. The scale cracks along the bend of the flange of the head and the tendency of the head to assume a hemispherical shape were also noticeable. On the basis of final failure and assuming that the working pressure for which the cylinder was designed was

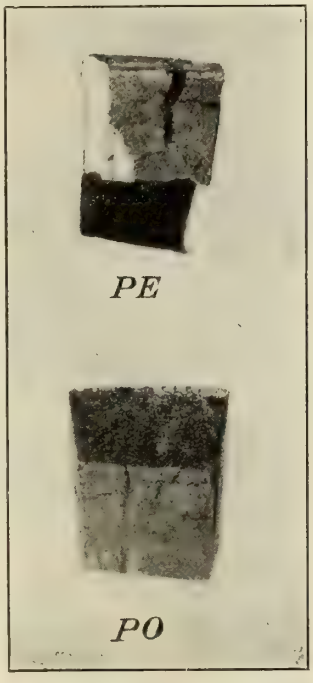

Fig. 13—End views of specimens PO and PE, showing cracks extended deeply into metal. Magnification 1.5.

185 lb. per sq. in. as in the other cylinders tested, the factor of safety is 10.28.

Using the same initial diameter as in cylinder No. 2 and assuming that the effective thickness of the acetylene-welded circumferential seam is the same as that of the shell material, this seam safely withstood a stress of 16,820 lb. per sq. in. of cross-section without any sign of leakage or distress. If the actual thickness of the weld is taken to be 0.442 in. as was found on carefully measured specimens of similar welds in cylinder No. 2, the stress safely withstood was 12,930 lb. per sq. in. The stress per linear inch of seam safely withstood was 5,715 lb., without any sign of leakage or distress of any kind.

Final Summary

Table 5 summarizes the results of the tests. It is somewhat difficult to make a comparison between the acetylene-welded and the forge-welded seams on the basis of tensile strength, because the stress on the acetylene-welded seam is a direct tension while that on the forge-welded seam is shearing. Possibly the fairest comparison is the load which the seam will carry, expressed in pounds per linear inch of seam. Table 6 gives the strength of the several joints, using the results of the tests on the five cylinders as well as those obtained by Professor Patterson. Even this is not an entirely fair comparison, because some of the acetylene-welded seams are thicker than others. The average stresses per linear inch of seam are as follows:

	At first leakage through lb.	At final failure of seam lb.
Forge-welded seams	3365	4168
Acetylene-welded seams	8080	10754

In considering the results here presented it must be borne in mind constantly that the object of the investigation was to compare different methods of constructing containers for anhydrous ammonia for use in refrigerating-plant practice. Even a comparatively small ammonia leak is sufficient to make the room in which it occurs untenable. If the leak occurs in a confined space where ventilation is poor, as, for example, on shipboard, the results may be quite serious. In boiler practice absolute tightness is not nearly so important as adequate strength against serious rupture, but it should be emphasized that in the case of containers for anhydrous ammonia, leakage constitutes failure.

From all of the data secured by the tests themselves and also by subsequent investigation and analysis it appears that the vessels having forge-welded heads are the least reliable. The entire

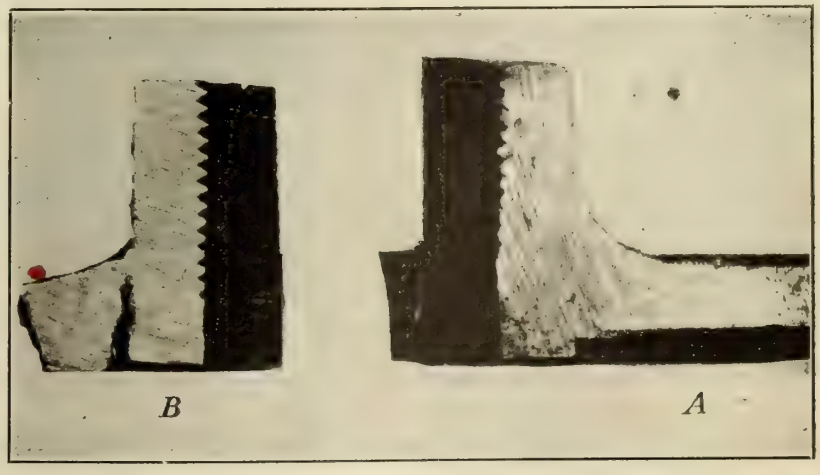

Fig. 14—Two pipe-coupling specimens. B is nipple of cylinder No. 2 which leaked through weld. A is sound nipple welding that did not leak.

circumference of the weld is likely to have incipient cracks where the union between the flange of the head and the end of the shell is imperfect. If the common shape of dished head is used it obviously must be inserted in the shell with the concave side outward in order to make a forge weld. Under the action of heavy internal pressure the curvature of the heads is reversed and this sets up a tearing or peeling action which increases the incipient flaws in the weld and leakage follows. This result is still further aggravated by the opening out of the crimped ends due to the spreading action of the head during reversal and the consequent expansion of the material just at the weld. Furthermore, it is quite likely that the dished heads are more or less distorted during the forge-welding process. Surfaces that are subjected to pressure on the convex side are in a state of unstable equilibrium and even slight initial distortion will result in excessive distortion at much lower pressures than would be carried safely. This was shown in the case of cylinder No. 3, in which one head was somewhat flattened when received at the testing floor. This head began to reverse curvature at 200 lb. per sq. in. The initial distortion undoubtedly contributed to its low resistance.

In the forge-welded specimens examined microscopically, evidence of burnt steel was found in all cases. In general, burnt steel may be expected in forge welds because the burning temperature and the welding temperature for steel are quite close together. Some time must elapse, and hence some cooling takes place, between the instant the pieces are removed from the forge and the time at which the welding actually takes place. It is essential that the pieces be at the welding temperature at the time the blows are struck. The comparatively thin pieces in question lose heat rapidly and this leads to their requiring a higher forge temperature than pieces of more compact form, thus increasing the danger of burnt steel. Burnt steel and overheated steel are very weak and brittle as compared to steel not treated so. When burnt steel is forged, cracks like those in specimen PE (Fig. 12) are formed. This action renders leakage under pressure and consequent failure easy.

Oxide inclusions along the surfaces joined by forge welding are practically inevitable. Where an oxide inclusion exists the union between the two pieces welded together is obviously imperfect, thus weakening the weld. If the forge-welding process is to be used it is recommended that decisive steps be taken toward much more careful temperature control. The work also indicates clearly that the best type of vessel tested was that made up of a seamless-pipe shell with acetylene-welded dished heads, convex outward. This construction places the welds where they have to sustain a minimum stress and eliminates the danger of a failure such as occurred in the cases of cylinder No. 4.

TABLE 5 SUMMARY OF TEST RESULTS

Cylinder No.	1	2	3	4	5
Shell	Flange steel, longitudinal seam acetylene welded	Seamless pipe	Seamless	Flange steel, longitudinal seam acetylene welded	Seamless pipe
Heads	Forge welded to shell	Acetylene welded to shell	Forge welded to shell	Acetylene welded to shell	Acetylene welded to shell
Pressure at first leakage, lb. per sq. in.	950	2000	1300	1700	1900
Maximum pressure attained, lb. per sq. in.	1450	2600	1380	1700	1900
Cause of final faliure	Leakage through forge weld	Leakage through acetylene-fitting weld	Leakage through forge weld	Rupture of acetylene-welded longitudinal seam	Leakage through acetylene-fitting weld
Factor of safety on first leakage	5.13	10.81	7.03	9.18	10.28
Factor of safety on final failure	7.85	14.06	7.46	9.18	10.28
Stress in longitudinal seam, lb. per sq. in.	34,400	....	....	40,500	....
Stress in circumferential seam, actual, at first leakage	....	13,620	....	28,300*	12,930
Same at final failure	....	17,690	....	28,300	12,930

*Caused final complete failure.

In the five cylinders tested there were two acetylene-welded longitudinal seams and six acetylene-welded circumferential seams, a total of eight important acetylene-welded seams. The authors were able to rupture but one of these, a longitudinal seam. Very slight leakage was obtained at one other, a circumferential seam. Of the four forge-welded seams every one failed by excessive leakage at pressures considerably lower than those safely sustained by the acetylene welds. There were a total of 28 pipe fittings acetylene-welded to the five cylinders. Leakage was observed through two of those, in each case finally resulting in failure.

The tests also indicate that the acetylene welds are likely to have occasional porous spots and that pinholes may often develop when high pressures are reached. They also indicate that the welds where fittings for pipe connections are joined to the vessel are almost as likely to cause failure as are the longitudinal and circumferential seams. The acetylene welds also have non-metallic inclusions, but they are more globular in form than those found in the forge welds and are also scattered in all directions through the material instead of being concentrated along the contact surface. They are therefore less likely to cause leakage.

The principal defects in the acetylene welds examined seem to be the coarse granular structure and porous spots obtained and the occasional poor adhesion of the welding material to the original plate. Poor adhesion may be due to the plate cooling below a good welding temperature, or becoming oxidized along the surface before the welding material is added. These defects suggest the following possible remedies:

(a) The plate should be heated for as short a distance ahead of the fused-in material as possible. This should render cooling less likely and reduce the chance of oxidation.

(b) The work should be done as rapidly as possible in order to reduce the grain size to a minimum. As low a temperature as possible, consistent with good welding, is desirable for the same reason.

(c) The weld should be cooled as soon as possible after being made, in an effort to reduce the growth of ferrite crystals.

(d) Possible oxide inclusions might be reduced by using a flame so adjusted as to be neutral or slightly reducing rather than oxidizing in nature. This would require some experimentation.

(e) Defects in welding attachment couplings to shells or heads, similar to those which caused the failure of cylinders Nos. 2 and 5 (see Fig. 14) could probably be avoided by scarfing the edge of the hole into which the coupling is set. While defects of this character can be avoided by careful workmanship, it would seem that scarfing would render the difficulty much less likely to occur. A scarfing tool similar to a pipe reamer could be devised easily.

(f) In the case of seams examined, poor adhesion was noticed in a number of cases, particularly at the bottom of the weld. This might be improved by scarfing both edges to be joined and carrying the bevel nearly if not quite to the bottom of the plate.

CATALOGUES

The Geometric Tool Co. has just issued two new catalogues, one covering their style D.S. die head as applied on single spindle automatics, and the other on the Jarvis line of high speed tapping devices and appliances, such as quick change chucks, collets and self-opening stud setters.

Practical Ideas From Practical Men

ACCURATE DRILLING SOLUTION

By R. Henderson

In the day's work in many plants drilling jobs are constantly arising for solution. Often times the men who must handle these problems have in their day's work a great variety of solutions to pass upon and as a result these problems do not get the expert solution they would get were they to be handled by men who study nothing other than driller problems. In the manufacture of accounting machines one of the very important operations is the making of the die plates which must punch the cards. The reason for the accuracy is that in the multiple printing each punch must accurately enter each die, and further, the cards must be accurately punched in order to register properly in the electric tabulating machine.

The plate in line cut which is one of a series is made of a high grade tool steel varying in thickness from ⅛ inch to ⅜ inch. Two problems presented themselves, one was the question of time for the drilling of the plate which took from 3 to 4 hours, and the second was accuracy. The tolerance between the two extreme holes was plus and minus .002 inches, while any two adjacent holes could not vary more than .0005 inch. The plate had 45 holes the long way and 12 rows across. As the holes were too close to drill every one, the best plan finally worked out to have 9 spindles drilling every fifth hole, making five operations to complete each row.

This plate was located on the upper table of the indexing jig which had an oil basin for cutting compound, by means of accurately located dowel pins, so that should the plate for any reason be removed, it could easily be replaced in its original position. This table was placed on a compound table which accurately moved at right angles. The threads on each screw were so cut that either one turn, or a multiple, gave the exact distance to be moved over. Inasmuch as the accuracy of the finished work had to be held to very close limits an interesting problem arose in the cutting and testing of the lead screw. Of course great care was also necessary in scraping in the sliding members.

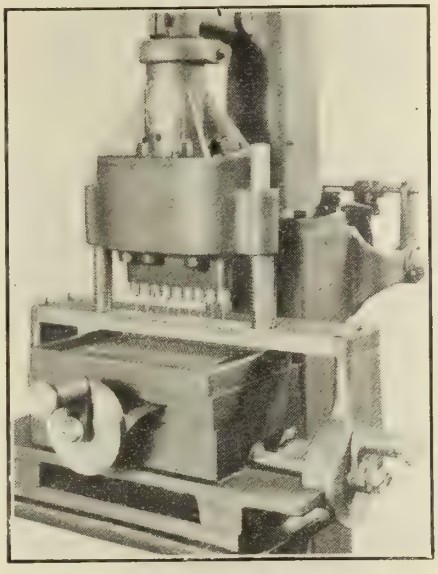

Fig. 2—Interesting design of multiple drilling machine.

Across the top of the jig is carried a heavy steel plate in which is located the liner and the slip bushings which guide the drills as near the work as possible in order to maintain the requisite accuracy. From this plate two heavy hardened and ground guide rods rise to keep the head and jig in alignment at all times. The head itself is counterbalanced in the column of the driller, but the springs are added to assist.

The head is of the usual sturdy construction with sufficient metal to keep all parts in alignment. This head is mounted on the high speed ball-bearings with automatic cam feed and return, so that practically the only duty of the operator is to index the jig and replace drilled parts. With this equipment the 540 holes in the plates were finished in twenty-two minutes, floor to floor, as against the previous time of three to four hours. The entire equipment was handled by the engineering department of the Hoefer Co., Freeport, Ill.

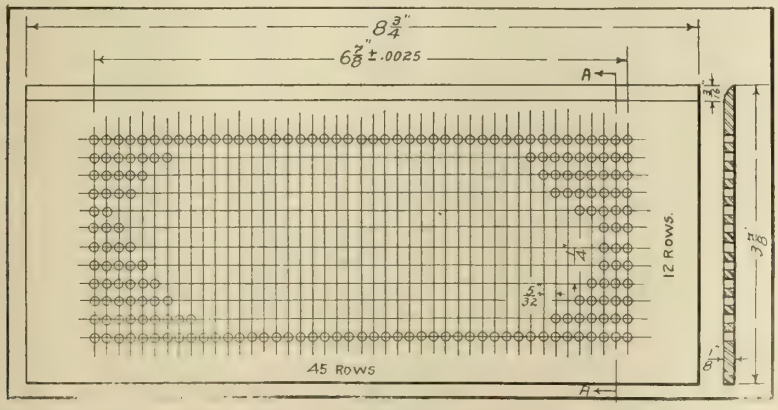

Fig. 1—540 holes drilled with an allowable variation between any two holes plus or minus .0005.

SHOW VISITORS AROUND YOUR PLANT

By D. A. Hampson

In this enlightened age, visitors are welcomed in most shops. Not loafers or back-door visitors, but bonafide visitors who come into the office, say they happen to be in town, and would like to see "how castings are made," for instance. A goodly proportion of present-day visitors are automobilists; they tour as one way of taking a vacation and in so doing they see much of the world while acquiring red cheeks. Sometimes the male members route their tour to pass through a town where is located a plant they would like to visit—more often, in passing through, the sign attracts and the tourist stops to visit while the female members go sightseeing or shopping.

Some shops do not extend the glad hand to visitors, fearing that they may carry away business secrets. This is an old fashioned policy—a boomerang policy, in fact. If there is actually anything that needs to be guarded, and it comes along the path of the inspecting party, it can be guarded or clouded by stopping the work temporarily or by throwing a pair of overalls across the machine just as a mechanic does when the whistle blows.

But the visitor who comes to the office, states his wishes, and identifies himself and his business connections is more apt to bring business than to "steal" ideas. He is equally ready to exchange courtesies when positions are reversed.

Not long ago a tourist was attracted by the sign, "National Electric Iron Co." atop a 50 x 100 ft. building in a city he was passing through. He stopped and went in, was courteously received and shown everything from coil winding to nickel plating. He also saw quantities of outside work being plated—the company have greater capacity than the iron business required. Now it happened that only three weeks later this visitor's own business ran into a job that required several thousand parts to be nickeled. Quite naturally he thought of the flat-iron business and put the proposition up to them: It resulted in a fine job for the platers and better delivery and lower prices for the buyer than he had been getting before on his plating work.

Two other instances of this kind came

to notice the past summer. In both the visitors were interested in an allied trade or branch and had no business to offer to the plant being visited. In both it happened that the turn of events brought these men into the position of prospective buyers of the very goods sold by the plants visited. Courtesy won and very satisfactory business connections were established. One instance was in the wire spring forming line and the other was in brass castings. So we can see that it pays to receive visitors. And it pays to have a sign on your building.

HOW MUCH FUEL DOES A CLEAN BOILER SAVE?

By W. F. S.

Here is an interesting and valuable chart for finding the fuel saved by keeping boilers clean. Simply zigzag across the chart three times with a straightedge or fine black thread, as indicated by the dotted lines drawn across, and the per cent. of fuel saved is found in the last column at the right—Column G.

For example, if the temperature of the chimney gases before cleaning was 580 deg. F., and after cleaning 480 deg., and if the heat value of the coal is 12,000 b.t.u. per pound, what is the percentage of fuel saved?

Connect the 580 (column A) with the 12,000 (column C) and make a note of the figure intersected in column B. In this case we find the figure in column B to be 70 per cent. Now begin at the 12,000 (column C) and run a line through the temperature difference (before cleaning and after) in column D, which is easily figured to be 100 deg. Continue the line until it intersects column E. Column E, you will note, is intersected at 3.8 per cent. Now from this point (column E) run through the figure in column F, which is the sum of the figures obtained in column B and E. In this example the sum is (70 plus 3.8 per cent.) 73.8 per cent. The continuation of this last line through column G gives the answer as 5.15 per cent.

The instructions on the chart itself tell just what to do as you go along. Each column is fully explained, excepting column B and E, which are to be added together for use in column F. In zigzagging across, the second line from column C to column E begins where the first line ended—at the 12,000 b.t.u., the 13,000, or whatever it happens to be. In this example it is 12,000 b.t.u. In the same way the third line, from column E to column G, begins where the second one ends. The writer has experimented with this chart to find which is quicker—the chart itself or the formula on which the chart is based. In every instance I found the chart to be much quicker. The only mathematical operation involved—adding two simple numbers—requires very little time or thought and can frequently be done mentally.

Not long ago I developed and published a formula for computing the fuel saved by cleaning boilers. This formula met with considerable approval. One correspondent, however, asked if I could alter the formula and get rid of the "boiler efficiency factor" which was contained in the formula. Many operators of boilers haven't an inkling regarding their boiler's efficiency, and as soon as one begins to talk efficiency to them they shrug their shoulders and give up the task as hopeless. With this correspondent's suggestion in mind I sought out some good representative steaming tests where I knew the firemen and engineers did the best they could and derived this formula:

$$\frac{100\ (T-t)}{0.22H-0.37T-t} =$$

Per cent. of fuel saved, assuming 18 pounds of air per pound of fuel.

Where

T=the temperature of the chimney gas before cleaning;

t =temperature of chimney gas after cleaning, deg. Fahr.;

H=heat value of fuel in b.t.u. per pound.

This is the formula upon which the chart is based. It contains three most important factors, all of which are usually known or determined without great effort. T and t can be found by means of a pyrometer or a thermometer properly placed in the gases. If a thermometer is used don't place it close to any comparatively cool body or the bulb will radiate heat so rapidly as to affect the reading considerably. The heat value of the coal, H, can be ascertained with fair accuracy from Bureau of Mines publications, which list the heat values of coals mined all over the United States. Naturally the chart is subject to criticism. It is not claimed to be perfect. No boiler efficiency formula can be expected to be perfect, containing only three factors, as this one does. It is simple, however, and that is a thing that is always wanted. It shows clearly that a cleaning operation should reduce the temperature as much as possible. The lower the final temperature the better. It also shows that it is desirable to use high-quality coal—coal of high heat value. The lower initial temperature and the higher heat value of the coal, the more difficult it is to save coal, because under such conditions the efficiency of the boiler is already high.

The range of this chart is great enough to include most boilers. The efficiencies range from 50 to 100 per cent. The maximum temperature decrease is 200 deg. F., which is sometimes exceeded but seldom is an average decrease. Column G shows that the chart will compute savings all the way from 2 to 15 per cent. Should your problem be so unusual as to fall outside of this chart, which is improbable, recourse may be had to the formula which is given above.

DRIVING OUT TIGHT BUSHING

By C. Howard

A job came in the shop one day in which there was a bushing fittted in a blind hole very tightly. There was not enough space at the bottom of the hole to get a hook of sufficient strength to pull the bushing out. After several attempts had failed, a rod was turned to fit quite accurately into the hole. The hole was then filled with oil and the rod inserted and driven in against the heavy oil with a hammer. The pressure exerted was transferred to the inner end of the bush which was forced out with very little difficulty.

When using a vertical belt, have no more center distance than absolutely necessary—the weight of the belt reduces the efficiency of the drive.

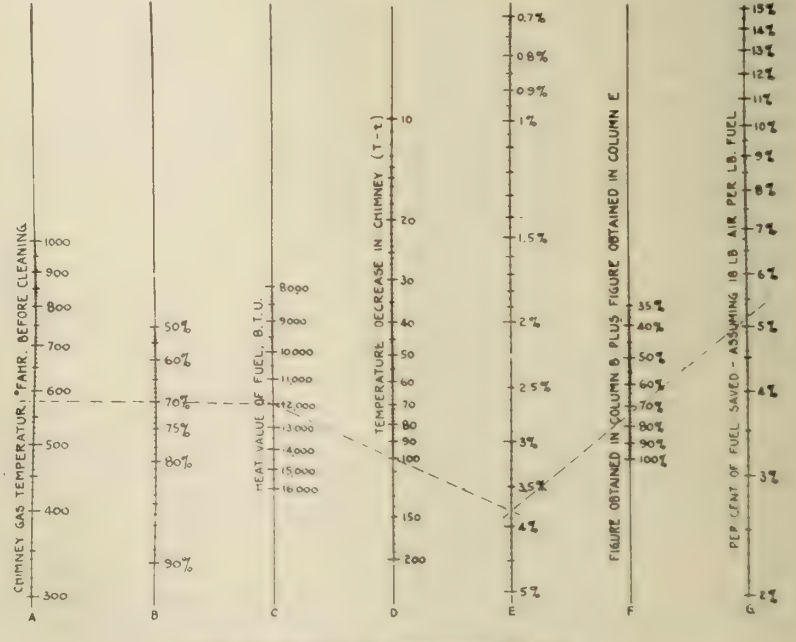

Chart for finding the consumption of fuel.

New Things in Shop Equipment

48-INCH PLATE SHEAR

An exceptionally large plate shear, designed for heavy duty, has been developed recently and placed on the market. It has a capacity for shearing 1 in. steel plate 48 in. in width. The shear is arranged for either motor or steam engine drive. The camshaft is 11 in. in dia. and is fitted with an automatic releasing clutch, either for stopping at every stroke or arranged for continuous operation. The machine has a weight of 55,000 lbs. It is manufactured by the Reading Foundry Co., Reading, Pa.

COMBINATION CLUTCH AND BRAKE

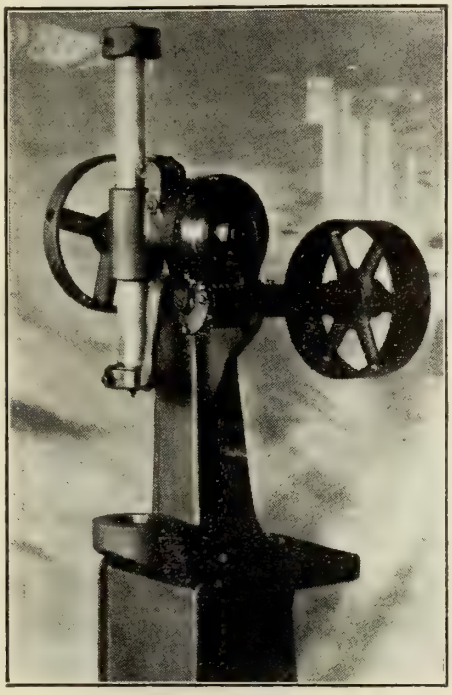
To facilitate the operation of tumbling barrels and guard against accident, a combination clutch and brake has been placed on the market. The device is of simple construction and controlled by a single hand-operated lever. The clutch is engaged by shifting the lever towards the mill, and when moved in the opposite direction the brake is brought into operation. The loading and unloading position is quickly obtained and the brake prevents possible creeping when recharging. Even when the barrel is unevenly loaded it cannot move when the brake is set. These devices are made by the Whiting Corp. of Harvey, Ill.

ELECTRIC GLUE POT

An automatically-controlled glue pot has recently been offered to the trade. The heating medium for the pot may be obtained from an electric lighting circuit by simply connecting and turning on the switch. The heat is maintained at a temperature ranging between 140 deg. and 150 deg. F. The proper degree of heat is assured without cooking or injury to the holding properties. The pot may be employed as a water bath or dry heat as desired, and may be adapted to the melting of such materials as wax, pitch, or other substances requiring a definite working temperature. The heating element is in the bottom of the pot but provision is made for protecting the bench from the heat. The temperature is controlled by means of a thermostat. The water pot is above the thermostat, and the glue container inside the pot. The glue container is of cast aluminum and fitted with lugs that prevent the floating of the inner vessel when only partly filled. A part of the bail extends across the top of the pot, which serves as a brush wiper. A temperature gauge is fitted to the pot. This device is the product of J. D. Wallace & Co., Chicago, Ill.

POWER BENCH BROACH PRESS

A machine, particularly designed for the broaching of small holes, has been placed on the market recently. The machine has a maximum stroke of 14 in.; develops approximately two tons pressure; will take work up to 6 in. in diameter; the table is bored 2½ in. diameter central with the rim; size of driving pull 10 in. diameter; 3 in. face. The power is transmitted through a steel worm and a bronze worm gear. The machine is fitted with an automatic stop and the movement of the ram is controlled by a positive jaw clutch, which is of steel and is hardened. The return movement of the ram is by means of a counter-weight. The machine also can be operated as a hand machine, the hand wheel having hollow spokes to receive a leverage bar. Height of the top of the work table to the floor is 36 in. The pedestal shown has an oil receptacle and this can be connected with an oil pump when required. Machine weighs approximately three hundred and fifteen pounds. It is made by the American Broach and Machine Co., Ann Arbor, Mich.



SENSITIVE DRILLING MACHINE

A new line of highspeed sensitive drilling machines, adapted to either bench or floor work, has been placed on the market recently. They are made with one, two, three or four spindles. The spindles are entirely enclosed by telescope sleeves to prevent oil from being thrown upon the work or on the operator. Norma ball bearings are fitted to the spindles which may be operated at a speed of 4,000 r. p. m., without shock or vibration. Independent ball bearings are provided for the driving pulley. All bearings are conveniently adjustable so as to maintain tightness and alignment in service. On the column type the table has a vertical movement of 30 in. and is counterbalanced inside the column. The table is accurately set to central position by means of a planed line on the column. The spindle head has a vertical adjustment of 6 in. When using chucks the machine has a capacity for drilling 5/16 in. holes. Larger holes may be drilled by using taper shanks directly inserted in the spindle. Rack movement of the spindle is 2-5/16 in., the reaction being taken by a concealed coil spring.

Driving belts are endless and tension regulated by moving the auxiliary countershaft. These machines are manufactured by the Sigourney Tool Co., Hartford, Conn.

CYLINDER BORING MACHINE

A portable machine primarily intended for reboring automotive cylinders, and known as the "Superior" re-boring machine, has been offered to the trade recently. It is of rigid construction and will economically handle any work within its range. The bed plate to which the cylinder is secured while being bored, is provided with two housings that carry the two stiff steel posts on which the cross rail is supported. The boring bar is held between two centres which retains it in accurate alignment when tools are working on hard or soft spots, ports and clearances. Supporting centres are of tool steel, tempered and round. The rigid construction of the cutter head assures accurate service when working on cylinders that are worn out of truth. The cutter head contains six inserted blades adjustable simultaneously by means of a hand wheel. All blades are made of high-speed drill rods and well tempered. The helix of the cutters resists the tendency to cut into the wall of the cylinder. Cutter heads provide a range of size from 2-13/16 in. to 4⅛ in. dia. A special arbor is supplied for setting the cylinder centrally with the cutter spindle. Four different feeds are available by means of a star wheel which may be set to engage with different rollers. Both star wheel and rollers are hardened. The driving motor is attached to the cross rail and gears are of helical design and hardened. These machines are made by the Production Machinery Co., Jackson, Mich.

KRITISCOPE FOR TESTING STEEL

An instrument for determining the critical point in steel has been developed and placed on the market recently. These points that occur when the part is being heated can be detected magnetically, as it is a characteristic in steel to lose its magnetism as soon as the lower point is reached and the rearrangement of the structure takes place. The critical point is indicated when a loss of magnetism is registered with the instrument in contact with the heated steel. When it is desired to make a test the tool is touched to the steel and then withdrawn slightly. If the bar or indicator remains in contact with the work, the latter is still magnetic and requires further heating. The part of the instrument that comes in contact with the heated steel is not a magnet, and can therefore be heated without danger. This indicating bar receives its magnetization by induction from a permanent magnet located within the body of the instrument. The magnet itself is protected from the heat by the walls of the body. The Kritiscope does not register the temperature of the furnace or the piece. The device does not require calibration and is not affected by vibration or rough handling. The instrument is self contained and the reading can be made quickly and directly to ascertain the condition of the steel and the proper time for quenching it. These instruments are made by Herman H. Sticht & Co., New York.

SPEED INDICATOR

A speed indicator that accurately determines and registers the revolutions of shaftings, motors, etc., in either direction, and measures both high and low speeds equally well, has just been placed on the market. The indicator registers up to 5,000 revolutions by every 5 revolutions, although speeds much faster than 5,000 r.p.m. can be very readily determined. The two arrows on the face of the dial indicate the figures to use for the different directions of rotation, eliminating any confusion. The figures showing through the small round windows on the dial read every 5 revolutions direct. The small inside dial reads every 100 revolutions. This dial is quickly turned to 0 for repeated use by the knurled knob on the back of the indicator. The fibre handle is especially shaped to fit the hand and the fibre is an insulation against electricity. The working parts are enclosed in a heavily dull-nickeled case. Three points are furnished as shown; a steel point for ordinary speeds and rubber points for high speeds. All projections, rough edges, and corners which might interfere with its ready use have been eliminated. It is a neat, light, and convenient indicator, easily handled.

This instrument is manufactured by the Brown and Sharpe Mfg. Co., Providence, R.I.

TAKE-UP WEDGE FOR HAMMER HANDLE

A tapered, threaded plug intended for retightening the handle in the head of impact tools, such as hammers, axes, hatchets, etc., has recently been placed on the market. The thread is of uniform pitch throughout its length and a slot is located on the large end for use of a screw driver. The design of the plug not only provides for tightening the handle when first inserted but provides an adequate means to maintain the firm setting almost indefinitely. When first placed in a hole is drilled and the screw driven in. Subsequent tightening is accomplished by a slight turn of the screw. This plug has been developed by Fayette R. Plumb, Philadelphia, Pa.

HACK SAW FRAME

A hack saw frame with the handle so positioned as to afford a comfortable grip has just been placed on the market by the Consolidated Tool Works of New York. The construction is said to provide for a powerful stroke without undue fatigue to the operator. The frame is made entirely of nickel-plated steel, with the exception of the wooden handle. The wing nut for tightening the blade is located at the handle end of the frame where it is out of the way. The blade may be placed to operate in any one of four directions.

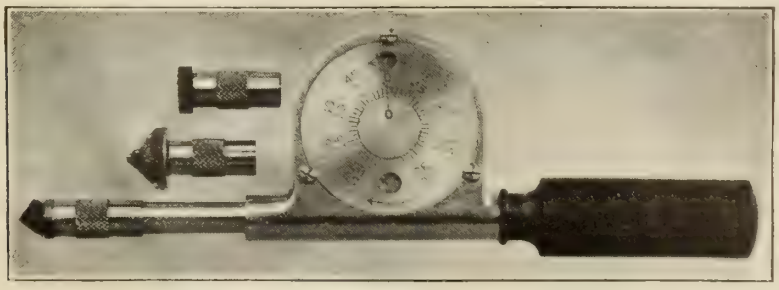
FLEXIBLE SHAFT COUPLING

A new type of flexible shaft coupling in the form of a machine cut spring has been placed on the market recently. The device is primarily intended for shafts up to one in. in dia. The body of the coupling is formed from a cylindrical tube of a quality of steel suitable for power transmission on account of its toughness and high elastic qualities. Hollow-head safety set-screws are employed for securing the coupling to the shafts. These couplings are especially adapted to direct connection on light-duty motors for driving small machines where shafts may be slightly out of alignment and it is necessary to reduce bearing friction and absorb shock. The coupling allows for both angular and parallel misalignment. However, shafts should be as nearly in line as possible. Larger couplings of similar design are also made. These are made of rectangular chrome-vanadium steel bars tempered to provide high elasticity. These coils are mounted, one within the other, on machine steel plugs. On the ends of the coil are shrunk steel headers, binding the parts into a continuous flexible unit. Flanges are attached by means of safety cap screws. These cut-spring flexible couplings are made by the Steel-Flex. Coupling Corp., Detroit, Mich.

LAYING-OUT AND DRILLING MACHINE

A machine intended for toolroom use in conjunction with Johansson compound slide and blocks, has recently been developed and placed on the market. It makes a complete laying-out and drilling machine for the spacing of holes in such work as dies, jigs, templates and master plates. One of the features of construction is the rigid arm extending below the point of the drill so that a bushing of the correct size for the drill can be located just above the surface of the work, thus preventing the drill from springing. The machine table is adjustable for height so that work of any size may be placed beneath the bushing. The head of the machine can be moved through 360 deg. The spindle housing and guide arm are cast integral, assuming accurate alignment. Guide bushings are lapped and ground concentric with the hole. Chrome-nickel ball bearings are provided on spindle and pulleys. A compensating spring idler is fitted to machine to maintain a uniform belt tension. Speeds range from 400 to 4,300 r.p.m. By using a single lip cutter, the machine can be adapted to routing or milling. The head may be disconnected and attached to the column of a milling machine in a few minutes. In drilling small holes in jig or tool work, any number of holes may be accurately drilled by use of the Johansson blocks. The machines are made by E. L. Krag and Co., Chicago, Ill.

Elevator lubrication is considered by many authorities to be a lubricating problem in itself. Few other types of machinery involving the same mechanical principles operate under such severe conditions, where starting and stopping is continuous and generally under heavy load. Especially does this hold true in the electric geared traction machine where the worm has to exert a starting torque approximately three times the normal, doing this when the oil has probably been entirely squeezed out from between the worm and gear.—Lubrication.



Direct Reading Speed Indicator.

Important Export Prospect

THERE IS marked improvement in trade between Canada and Australia and New Zealand. A preferential tariff arrangement is now proposed which will further develop trade relations. The motor car industry seems to have derived the greatest benefit from the activity in this direction. There is no doubt that the move to establish greater trade intimacy with these colonies will be closely watched by American firms and tend to strengthen whatever inclination they may have to locate their exporting plants in Canada. A large demand for cars for Australia already exists, and business of this kind encourages the feeling that other lines, particularly products of iron and steel, can be equally successful. There is some movement in agricultural implements, although reports indicate that Australians have developed an industry of this kind and it has now to be demonstrated whether it can compete with import lines. Hardware, small tools and machine tools have an opportunity in this field and there is no doubt that manufacturers are keen on the prospect.

Given favorable bases for trade, an important factor in its growth will be regular shipping facilities. In this connection an exclusively Canadian service will undoubtedly prove of great value.

For Better Cost Accounting

IN A RECENT talk to business men, a banking authority dealing with information secured in an investigation of industrial accounting methods, declared that it was as surprising as it was deplorable that so many concerns with promising futures, had not equipped themselves properly in the methods of correct cost accounting. In many cases, it was found that the system in use was that which had been employed in the early stages of the business and had become inadequate.

It may be argued that a system that had answered the purpose during periods of growth could hardly be criticised at the present time when operations were running below normal. So long as manufacturers are satisfied that their equipment in this respect is the best available for the purpose, there is nothing more to be said, but where they sense the fact that the matter should have their attention and that greater efficiency is easily possible, they cannot afford to allow the matter to slide. There is sometimes a reason behind assertions that So-and-Co does not know what it is costing to run his business. He may have a very definite knowledge, if he has been in business for any length of time, but the point is to make the most profitable use of that knowledge.

A series of articles on cost accounting was begun in this paper with the issue of Nov. 9. They are prepared by a practical accountant engaged in the office of a machine tool manufacturer and should prove of great practical value. Discussion or suggestions upon the subject are welcomed.

May Encourage Relative Attitude

WHILE THERE appeared to be no outstanding national issues involved in the recent American elections, the result is not without interest to the Canadian manufacturer. The Republicans suffered a decided slump, and it was not altogether unexpected. Recent utterances by American business men indicated that the ship of state was not being handled to the entire satisfaction of industrial interests by the Harding administration.

The great showing made by the Democrats may be attributed largely to the cumulative pressure of so-called local questions. The current appeared to run strongest when high tariff policies threatened industrial prospects. New York State was an illustration of this. Here Governor Miller, who was big enough to be mentioned as a presidential prospect, was defeated by Al. Smith, a former governor.

It is claimed that the larger industrial interests have not been pleased, either on the tariff policy of the government, or on its attitude in international affairs in general. There seems to be some feeling that while it may be good business to avoid entangling alliances abroad, it is equally good business to discourage the development of what is described as an extreme insularity. While it was claimed on one hand that desirable goods always found a market, it seems to have become equally evident to economists on the other side that, in present conditions of world affairs, selling without buying, in outside trade, was out of the question. World intercourse, on a profitable basis, can hardly dispense with inter-responsibility. This question, in its national aspect, did not have the same local bearing or appeal as other matters such as labor, prohibition, soldiers' bonus, and transportation, but there is reason to believe that it has been the subject of serious thought by men of world outlook.

One thing may come of the election; it may demonstrate to the Harding administration the advisability of the same sympathetic relative attitude that worked so satisfactorily during the disarmament conference.

"THERE never was a time when business newspapers could do a better stroke for the world than they can to-day by bringing it home to their readers and the great public that all the peoples profit by the peace and prosperity of each other. They are the most practical of internationalists and through the sensitive machinery of the market can estimate from day to day the reactions of policy and the supreme value of a settled order in the relations of states. They, better than anyone else, can realize the fallacy of the view on which nations have too often acted that what is one nation's gain must be another's loss. The world as we see it to-day is largely what politicians and statesmen have made it. Is it not time for the business man to take a hand?"—C. P. Scott, Editor, "Manchester Guardian."

Canadian Furnaces Drop Pig to Meet Competition

Domestic Metal Reduced $2.50—Better Than Buffalo Price—English Iron Covers Eastern Demand for Time—Record Ingot Production—Using Canadian Cars to Solve Shortage

THAT production of steel ingots for the present year will surpass that of last year by 75 per cent. and that of the two largest tonnage years before the war, 1912 and 1913, by 10 per cent. seems evident, according to reports from Pittsburgh. Should production continue during November and December at the October rate, the year's ingot production will be close to 34,000,000 tons, or 76 per cent. of estimated capacity.

High cost of material is now the important item in production, not only in the United States but also in Canada. Coal and coke are still high. For example, Pittsburgh quotes Connellsville coke at $7 to $7.50 as against an average of $3 in January and February. In this region there has also been a wage advance of 40 per cent.

There is much talk of car shortage and cases are known in which, to secure a supply of much-needed material, Canadian mills have made Canadian cars available to American roads. In one case, in the past few days, a whole train of cars was offered with the understanding that they might be used for ore from Ashtabula to Pittsburgh. However, in this instance, the cars might have solved the difficulty, but there was a shortage of the material required. While the car supply in Canada is none too sufficient, it apepars that the railroads are in a position to co-operate with influential customers.

While pig iron production was at a very low rate in April there has been an improvement to a basis of 70 per cent. of capacity. Customers, however, are buying only for pressing requirements as there has rarely, if ever, been a time when it was plainer that recessions in pig iron prices are expected. In order to meet the reduced prices of Buffalo furnaces domestic furnaces announce a drop of $2.50 per ton. This brings the Canadian market price down to $33.80. This compares very favorably with the Buffalo figure of $29 for 2x foundry iron. The Canadian buyer must add to this a sales tax of 3¾ per cent.; duty $3 80 per gross ton and freight of $3.30, a total of $7.10. This, added to the new Canadian figure, makes domestic pig a far more attractive proposition. The market, however, is not strong. In the East, there has been considerable buying of English pig iron for temporary requirements.

In non-ferrous metals, tin at present holds the spotlight by reason of the rather bullish tendency of the British market. Speculation has sent prices to high levels and, in spite of frequent fluctuations, these are being fairly well maintained. The Canadian price ranges from $40 to $41.

Wholesalers of ingot metals are preparing to protest to Ottawa because of what they consider an unfair distribution of sale tax. They point out that under the present arrangement there is an import tax of 3¾ per cent. and a resale tax, from wholesaler to manufacturer, of 2¼ per cent. But the large manufacturer finds that he can save the latter sales tax by buying direct from the manufacturer. This cuts the dealer out of the best part of his business and leaves only that part which has to do with the small foundries who cannot afford to carry stock. Another fine point and one that appears difficult to understand is, that scrap material sold from a manufacturer to a wholesaler for re-conversion into briquette or ingot form, carries a sales tax, while material purchased from a public utilities company is tax free. The ruling in the matter is that the latter has reached the ultimate consumer while the former has not. Ottawa, it is said, will shortly learn something about the problems of the metal business.

There is a strong demand for boiler tubes. The market for sheets is much easier, owing to large supplies coming from British mills.

Toronto

November 15

WHILE iron and steel markets are operating along lower levels at present, than in September and October, demand seems to be fairly steady. It will justify the conclusion that business improvement has been encouraging since the first of the year. There were unsettling influences but these seem to have had no fundamental effect. This is a good sign and indicates that the demand was based on actual industrial requirements rather than on speculative prospects. There has been definite reason behind all buying movements, even though this has resulted frequently in that conservative process known as buying from hand to mouth. Building operations, however, have accounted for a fair growth, and explain the somewhat active market in structural material up to the beginning of the present month, when there was a seasonal decline. The motor car industry has also been a strong department, and while the placing for next season's requirements has been a little backward, steel interests state that a slightly higher tonnage than was called for last year is indicated. Competition in the cheaper cars is developing a keen edge and it is predicted that car prices will reflect every advantage on raw material that the market can offer.

Iron and Steel.—A very quiet market in steel sheets is reported. There is almost an over supply on certain items, due to some extent, to imports from British mills. Dull Canada plates are an example. It is stated that supplies that should have been here three months ago are now available, and this has made for a very easy market. The same applies to other lines of sheet steel. The market is exceptionally well covered and prices are off from the levels of a month ago.

Boiler tubes have an active demand at the present time, and prices are firm, as a rule, but there are cases when competition is said to have caused a break away from stable quotations. For example, one dealer quoting $29 on a three-inch lapweld was confronted by the fact that a competitor had quoted $3 better, and had announced that it was their policy to quote easier prices at this time of year. The natural conclusion is that there are much heavier stocks in some quarters than in others. When conditions such as described exist, it is also responsible for the tendency on the part of buyers to bargain or dicker for what they suppose to be an advantageous price. As a rule, however, the average price from month to month represents a fair degree of stability as compared with base quotations. Current iron and steel quotations:

Iron bars	3 25	3 40
Steel bars	3 25	3 40
Reinforcing bars	3 15	3 25
Steel hoops		4 75
Tire Steel		3 50
Spring steel	7 00	14 00
Band steel, No. 10 gauge and 3-16 in base		3 90
Small shapes		3 50
Sheets, black, No. 28		5 10
Sheets, blue ann., No. 10		4 20
Canada plates, dull, 52 sheets		4 90
Canada plates, all bright		5 40
Galvanized Sheets, No. 28		6 25

Pig Iron.—Another reduction in the domestic price of $2.50 brings the price from $36.30 to $33.80. Easier quotations by Buffalo furnaces are the cause, largely, and at present figures domestic furnaces are well below the so-called nominal of $29 at Buffalo. When sales tax of 3¾ per cent., freight $3.30 and duty of $2.80 per gross ton, a total of $7.10, are considered, the concession represented in the new figure is obvious. Eastern foundries are reported to have stocked up with British pig, although it is evident that there will be a certain

amount of domestic iron in constant demand in order to ensure proper mixtures.

Non-Ferrous Metals.—Tin is still a centre of considerable speculative interest. There has been some fluctuation, but advances have been fairly well maintained and may go higher. Copper is quiet, lead prices remain firm and zinc markets continue to show strength.

A movement is developing among dealers in ingot metals to strengthen their protest to the government in connection with what they claim to be an unjust distribution of the sales tax. These dealers perform a useful purpose by carrying stock for the small foundry which cannot afford to tie up money in large stocks and hence buys as he requires. They also supply large manufacturers, and during the war were the sources of supply to many firms who could not adjust their credits to the carrying of heavy tonnages in these materials. Under the present arrangement of the sales tax, there is an import tax of 3¾ per cent. and a resale tax, from dealer to manufacturer, of 2¼ per cent. But the large manufacturer finds that he can import direct and pay only one tax, and that he can save the dealer's profit, which, however, is a very small percentage. Thus, the wholesaler loses most desirable business and is confined to small foundries. Many of these find that they cannot very well compete with the larger man who can afford to carry stocks of ingot metal.

Another fine point, and one that is hard to understand about the tax law is, that scrap sold from a large manufacturer to a wholesaler carries with it a sales tax, while scrap purchased from a public utilities company carries no tax. The ruling is that such material must carry a tax until it reaches the ultimate consumer. When he rejects it as scrap, it escapes taxation. These are hair-breadth distinctions and have added to the hazards of the metal business to such an extent that there are those who consider the advisability of stepping out. It is felt that transactions involving the junk dealers or small wagon dealers would show some very liberal interpretations of the tax laws. Large metal men are carrying their grievances to Ottawa, where there does not seem to be a very practical knowledge of the metal business among so-called tax experts.

Current prices on non-ferrous metals:

Lake copper	17 25
Electrolytic copper	17 00
Castings, Copper	17 00
Tin	41 00
Lead	7 50
Spelter	9 50
Antimony	8 50
Aluminum	22 00

Old Materials.—There is a lack of activity in this department which, in a sense, is explained by the pig iron situation. There has been little market in the latter pending an expected price adjustment, hence furnaces maintain that there must be a drop in scrap. The dealers in this material have been holding firm, but there may be a slight concession at an early date. The entire list seems to be at a standstill, with very light offerings or demand. Dealers' average buying prices:

Copper, light	9 00
Copper, crucible	11 50
Copper, heavy	11 50
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	7 00
Red brass turnings	7 00
Yellow brass turnings	5 25
Light brass	4 50
Medium brass	6 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00

Copper and brass products indicate a fairly strong market. While this is a department of industry which as a rule, has to do with such lines as chemical equipment, fire extinguishers, etc., the Christmas season opens up a demand in other directions and this explains a certain activity at the present time. Sheets and tube prices are firm, but there is some difficulty in securing supplies.

Machine tool manufacturers and dealers report good enquiries but no marked development in actual business. There has been sufficient in all lines, however, to warrant improvement in the staffs at many of the shops and the general feeling is that business tends toward a better record than earlier in the year.

Montreal

November 15

NO CHANGE in prices is reported this week and orders continue to come out for general steel commodities in a satisfactory manner and quite as good as during the last two months.

Iron and Steel.—Notwithstanding reports to the effect that railroads are getting the better of the car shortage, the difficulties of obtaining supplies from American suppliers are becoming severe. Embargoes are in effect in all directions and it is with the utmost difficulty that permits can be obtained for the forwarding of shipments. No relief is promised until a plentiful supply of suitable equipment is released from coal traffic. The result is that many commodities which are dependent upon American suppliers are becoming scarce in warehouses and manufacturers are having a hard time of it in obtaining delivery of sufficient supplies to satisfy their needs. Current prices:

Iron bars, base	3 15 to 3 25
Steel bars, base	3 15 to 3 25
Reinforcing bars, base	3 15 to 3 25
Steel hoops	4 00
Tire steel	3 25 to 3 40
Spring steel	7 00
Band steel, No. 10 gauge and 3-16" base	3 65 3 75
Small shapes	3 40
Sheets, black, No. 28	4 75
Shets, blue, ann., No. 10	4 10
Canada plates, dull, 52 sheets	5 50
Canada Plates, all bright	7 00
Galvanized Sheets, No. 28	6 50

Pig Iron.—A reduction of $2.50 per gross ton has been brought about by the necessity of Canadian furnaces meeting the downward trend of prices in the United States, more particularly those in the Buffalo district. In this district the foundry trade, shows no improvement, manufacturers of specialities being the only purchasers of any considerable tonnage.

"This reduction," a dealer states, "will not be felt in the East, however, as there is still a difference in favor of Scotch iron and consumers here have covered for their requirements over the next few months. The large recent importations of Scotch and English iron, together with tonnage still to arrive by the last direct vessels, presently, will provide a supply sufficient to cover the needs of local foundries well into the winter. It is now much easier to obtain supplies of foundry coke and the price has dropped off considerably. A difference of $3 to $4 per ton has been noted this week." Current prices:

Algoma, No. 1, car lots on tracks, nominal quotation		36 15
Summeriee, 30-ton lots, dock	35 00	
Carron, 30 ton lots	35 00	
Do., 5 ton lots, ex. warehouse	40 50	

Non-Ferrous Metals.—Commenting on prevailing conditions, the British Metal Corporation (Canada) Limited, have this to report:—

Copper.—Copper seems to have settled around 13⅞c. Domestic enquiry in the States continues fair, but there has been a large falling off in demand for export. This can be accounted for by the recent heavy depreciation of French and German exchange.

Tin.—Prices on the London market have fluctuated considerably; the opening of the week saw a new high for the year of £187-7-6, but this level was not maintained and the close was at £184-2-6 for spot and £184-15-0 for forward. Fluctuations are bound to occur on a rising market with a speculative element and though the close is lower than the opening there is a net gain over last week and the upward movement is therefore still maintained. As to the future, if optimism can be counted a gauge, prices should go still higher. Whether the grounds for this optimism are well founded or not, is another matter and on the face of the situation, it is difficult to see on what basis the "bulls" are working.

Lead.—There is no new feature of note and indications seem to point to a firm market for some while yet.

Zinc.—The London market has been very firm and good quantities have been bought on this side, thus strengthening the American market. Zinc stocks in England are negligible, so much so that it is becoming a costly business for "Shorts" to cover spot metal. Current local prices:—

Pittsburgh

November 15

PRODUCTION of steel ingots by the 30 companies which make monthly returns to the American Iron and Steel Institute was 2,871,415 gross tons in October, against 2,373,779 tons in September, showing an increase of 21 per cent., the months having the same number of working days.

Allowing for the producers not making monthly returns, October production by the whole industry was at the rate of 40,000,000 tons of ingots a year, or about 76 per cent. of estimated capacity, which is a trifle above the estimates made during the month. However, October, on account of weather conditions, is usually a month of production above the average, while the midwinter and midsummer months run below, hence the probability is that hardly as much as 76 per cent. of the productive units were actually engaged.

There has been, not merely a recovery from the curtailment in production produced by the coal strike, but a further gain, since the October production was at the highest rate since October, 1920. June, the best previous month this year, was beaten by 9 per cent. Should production continue during November and December at the October rate, which is somewhat improbable, the year's ingot production would be close to 34,000,000 tons. This would be 75 per cent. above the output in 1921 and more than 10 per cent. above the output in either 1912 or 1913, by far the two biggest tonnage years before the war.

Costs Still High

Steel mills find no difficulty in operating now, as regards supplies of coal and coke, and railroad movement of same, except for the very high cost. Connellsville coke, although it has declined in the past week, is $7 to $7.50 against an average of $3 in January and February. There has been a wage advance of slightly more than 40 per cent. in the Connellsville region. Pittsburgh district coal is $3.25 to $3 50 for steam, $3.75 to $4.00 for by-product and $4.50 for gas, against free offerings before the strike at $2.25, and some sales at less than $2. There has been no wage advance in that direction, the remarkable thing being that the old wage scale was continued.

Labor shortage at steel mills is still talked of, but does not seem to be as serious as a month or two ago, and the advent of winter weather, curtailing outside operations, will no doubt give the mills and furnaces a still better supply.

There remains much talk of car shortage. Mills have to make great efforts to secure enough cars for shipping finished product, but they are succeeding, as shipments are fully equal to production while the moderate accumulations of steel that developed when the car situation was at its worst are gradually being reduced.

Supplies of finished steel products reaching jobbers and manufacturing consumers are apparently adequate except in the case of butt weld merchant pipe, both black and galvanized. In these lines there is much pressure upon mills for heavier deliveries, and mills would probably produce more if they could secure more cars.

Pig Iron Production

Production of pig iron was down to 25,000,000 tons a year at the end of August, the lowest rate since April 1, while the rate now is about 32,500,000 tons, or between 70 and 75 per cent. of capacity. Current production appears to be adequate for present requirements, as some of the steel interests are offering pig iron in the open market, either openly through their own sales offices, or quietly through merchant firms, while the regular merchant blast furnaces can only occasionally effect sales of any size, consumers being apparently fairly well taken care of by stocks and by deliveries against old contracts. Consumers would, of course, buy only for pressing requirements as there has rarely if ever been a time when it was plainer that pig iron prices were in a recessive mood. Prices have declined only slightly from the peak, which was produced by a famine in fuel due to the coal strike. Taking an average of all prominent grades in the chief districts, pig iron prices are about $11 a ton or more than 50 per cent. above their average in the first three months of the year, before the coal strike. Meanwhile there have been reductions in freight rates, for which the furnaces were clamoring, and wage advances. The latter more than offset the former but the difference is only a few dollars a ton.

The valley market is quotable at $32 for Bessemer, $29 for basic and $29 for foundry, with $1.77 freight to Pittsburgh, Bessemer and foundry being down $1 a ton from last week. The market is stagnant, and prices would probably decline more rapidly if there were enough inquiry to produce active competition.

Coke Declines

Connellsville coke has suffered another break but is of course very high still. Furnace is off about 50 cents and foundry coke $2, in the week, furnace now being $7.00 to $7.50 and foundry $8 00 to $9.00, according to brand. Production has been increasing continuously, but the rate of increase has been somewhat less in the past two or three weeks than formerly. Most of the furnaces now in operation that depend on purchased cokes are covered more or less fully to the end of the year on contracts at about $8.00. On this account, and because the furnaces have considerable tonnages of pig iron to deliver to the end of the year on old sales they are not especially anxious to see either coke or pig iron prices decline. Some eastern furnaces, now idle, have intimated to coke operators that a $6 coke price would interest them. Operators consider $6 out of the question at present, as they can do better selling by-product coal.

Steel Market Quiet

The whole finished steel market is very quiet. There is little demand for prompt shipments since buyers have been receiving heavy deliveries lately on their old purchases, while there is not much buying for the new year. In bars, shapes and plates, now $2, as against $1.35 at the low point early in March, buyers naturally expect a considerable decline. In pipe, sheets and wire products advances were much more moderate and declines are hardly to be expected.

Steel Corporation Tonnage

The United States Steel Corporation's unfilled obligations stood at 6,902,287 tons at the end of October, equivalent to nearly six months of production at 75 per cent. of capacity. The business is not, of course, equally distributed in the different lines. Independents on an average have much leaner order books and some will probably be energetically seeking business within the next few weeks, making price an inducement if necessary. Having been hampered in their operations so long by the coal strike and transportation conditions, these mills are indisposed to allow lean order books to stand in the way of their operation.

The Steel Corporation's unfilled obligations increased by 173,944 tons in August, 741,502 tons in September and 210,680 tons in October. The September and October increases were due chiefly, probably wholly, to the large business done in rails and track supplies. Nominally this business was closed in September, as the rail price advance that caused the business to be placed became effective October 1, but practically some of the tonnage was not formally entered until October.

ELECTRIC FURNACES

Criticism of the electric furnace sometimes arises from wrong working, and this point is emphasized by several writers recently. For instance, says the Practical Engineer, it is pointed out that lack of adequate knowledge of the operations involved, have in many instances led to abuse of the electric furnace, and that certain mechanical and electrical weaknesses have jeopardised the successful operation of many furnaces. This leads to the proposition that properly made electric steel is superior to other grades of steel, as close control of the elements produce a product of chemical purity with great density and good physical properties. Competent control is not the only factor in the case. Consideration should be given to the cost of electricity, amount of power available, position for freights, costs of labour, &c. Records should be kept of units consumed per ton of steel produced, raw materials, refractories consumed, wear and tear on moulds and other operating details.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

A Poor Machine's a Bad Investment
It's false economy to let an old-fashioned or worn-out machine occupy valuable floor space and, quite possibly, affect the production of better machines. No need to buy a new machine either. Williams' re-manufactured machines are guaranteed as good as new for all practical purposes—and we've some specially good "buys" right now. Come and look them over.
Ask us to put your name on our mailing list for our monthly machinery list.

"THROW YOUR HEART ACROSS"

(Continued from page 20)

assurance that their destinies were assured from without. "The problem," said the speaker, "is not how shall we obtain our share, but how shall we make something worth sharing—not by capture, not by oppression, but by creation."

Sir James Barrie was frequently quoted as the apostle of hard work and of high endeavor. "The greatest glory that ever came to me," he had said, "was to be swallowed up in London, not knowing a soul and having to work until the stars went out." Very little reward had crowned his efforts, he had long been intimately acquainted with poverty, yet success finally came as the result of patient, courageous, cheerful effort. The speaker was assured that in spite of the problems that confronted Canada, problems that meant severe taxation, it was this high courage and cheerfulness which would win through in the development of her nationhood.

QUESTIONS AND ANSWERS

(Continued from page 25)

or so, but I am sure you will agree with me that this is the time in which to look around and for connections with a view to future possibilities. With your vast knowledge of firms in the Dominion, and of business conditions generally, I feel convinced that you will be in a position to materially assist in this connection.

"I might further mention that this matter is not really in my province; as I previously mentioned I am in charge of the export department, but I cannot forget my old allegiance to Canada, and I promised to give my directors all possible help that I can with a view of their doing business in your country."

Canadian Machinery welcomes letters from its readers seeking information that may be useful to them in developing export connection.

WHO PROFITS MOST?

A business can be built in a year, a month, even in a day; or the building of a business can command the greatest efforts of a lifetime. Craft, cunning, shrewdness, if diligently practised, may bring a result resembling success; but the constant application of sincerity, experience, and craftsmanship build for a success that all others can but imitate and envy.

A great thinker once said: "A business is but the lengthened shadow of a man." Whatever is your aim, your ideal —rest assured that it is known to all with whom you deal. Let no man be mistaken. Just as his true character will be known to his friends, so will the dominating idea behind his business be apparent in every transaction. The business that, spurning opportunities for mean profits, devotes its entire energies to the development and maintenance of a reputation and quality, often envies the seeming progress of a sharp-trading competitor. But such a business has none to envy. As by natural right, the superior quality of its product, honestly maintained, brings to it the friendship of each user. This friendship, multiplied again and again, builds a good will that is the greatest reward in business.

A business carrying the good will of its customers has little to fear. Temporary set-backs and interference it may have, but as long as its ideal is maintained, it will rise above small mistakes and errors. Let the directors of such a business keep their greatest asset and duty ever in mind, and profits will be satisfactory. Look at the businesses that have had more than ordinary success. Who are they? They are the firms that do more than their duty, that give more than agreed, that work for quality and service rather than for profit. For it is the rule that he profits most who covets profit least.—The Diston Crucible.

Fisherman's Ballast Leads to Great Ore Discovery

Newfoundland Has One of Most Valuable Iron Deposits in World —Richer Than American Fields—One Million Tons Per Year From Wabana—Easy Mining With Improved Equipment

Special to Canadian Machinery

ST. JOHN'S, Newfoundland.—Newfoundland has probably the most extensive iron ore deposits in the world. Their discovery in 1895 was the result of a fisherman's use of a piece of ore for ballast. The varieties include magnetite, hematite, limonite, specular and jaspery ores, but the only actual mining that has yet taken place in the colony is in connection with the hematite deposits on Bell Island, about twenty minutes run by steamer from the main land.

Though cruised by competent prospectors, even up to the present moment, the full extent of the mineralised areas of this little island is not completely known, but an estimate has been made by the "Besco" people, at present working the mines of Wabana, the capital of the island, that they can at least produce the enormous quantity of one million tons per year for several generations.

One of the best-known authorities on iron ores, in estimating the values (comparative) of the same deposits on the whole American continent, has placed on record that Bell Island areas will produce two thousand million tons, whereas the richest deposits of the United States, already known, have a capacity amounting to but one thousand, three hundred million tons.

58½ Per Cent. Iron

Formerly there were two companies working the Bell Island mines at Wabana—an Indian name meaning "where the light first shines." The pioneer company was the Nova Scotia Steel and Coal, which commenced operations in the year 1895, on properties which they had purchased from the original settlers on the land. In 1895 the Scotia sold to the Dominion Iron and Steel Company a portion of its holdings. The ownership of both concerns, which has recently been merged with the British Empire Steel Corporation, comprise five huge beds of ore, which up to the year 1921 has yielded over eight million tons.

The great success attending the development of these mines is largely due to the ready water transportation facilities that there are in Conception Bay, no less than to the cheapness in mining, as the ore at one time could be almost shovelled off the surface pilings into the holds of the ships lying at the piers ready to take it.

Besides the land areas, with a production capacity of still many millions of tons, operations have been carried on far beneath the bottom of the waters of the bay, in one place at as far as eight thousand feet, and at a depth of one thousand feet below the bed of the ocean. Thirty-five miles of these submarine areas were owned by the Scotia Company at the time of the merger and from these there is taken a quality of ore which is far superior to that found in the land deposits. The ore taken from these submarine beds has shown an average of over 58½ per cent. of metallic iron.

Much Ore for Germany

The work at these mines, at first, consisted of removing the surface earth, extracting the ore, the formation of which was in irregular cubes, and carrying it from the diggings to the side of the ship in waiting at the other side of the island, where it was loaded by means of shutes from hill to hold, the viaduct being on a sharply-inclined plane.

To-day all this crude method has been changed, for with deeper excavations an elaborate system of tramways for carrying and loading has been installed, and piers and wharves have been built which can accommodate ships of any tonnage. Most of the ore mined on Bell Island is used in the blast furnaces of the company at Sydney, Cape Breton, for the manufacture of steel rails and other construction material requiring steel as the basis of strength.

A great deal of the raw ore is now being exported to Great Britain and Germany, particularly the latter country, for since the close of the war, Germany has been taking huge cargoes weekly, and Custom House clearings show that the greater portion of the minings are now being shipped to former enemies by the British Empire Corporation.

It was not until the year 1895 that the first discovery of iron ore was made on Bell Island. The length of the deposits is three miles, and the breadth between a quarter and half a mile, on the land areas. On the removal of the covering turf and rock a horizontal band of ore is reached, which is worked like an open quarry. The first stratum is estimated to contain twenty million tons and is about six feet in depth. Then comes another rock covering of five feet, and this being penetrated, a second iron band of the same depth as the first is reached, containing about the same quantity of ore, so that the two first and original deposits as discovered are reckoned to have contained forty million tons, thus being practically inexhaustible.

There is no need of shafts in the working. Pickaxes, crowbars, wedges and a few charges of dynamite were sufficient to work the holdings at the beginning, for one unique feature about it is that th ore has a jointed cleavage, so that when taken out it breaks up into rhomboidal masses of various sizes, none, however, being of greater size than twelve inches by four. When extracted from the bed in this way it is shovelled into wagons with as much ease as coal is shovelled into a cart.

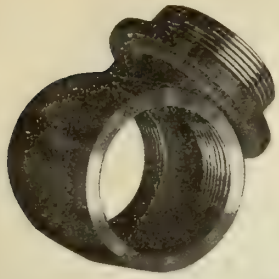
Since the early days of the working, all modern improvements have been installed and the manual labor is only that employed in digging the ore. Tramways now run from end to end of the workings and connect with the various piers. An endless cable worked by steam power moves the cars when loaded to a huge iron cage overhanging the water, through which the ore is dropped into the holds of the ships in waiting, so that loading is accomplished with great rapidity and expedition. When not completing cargoes the ore is dumped into piles, or pockets, which are always held in reserve for emergency contracts or accepted orders coming in with the legend "rush" crossed on them. It would be very difficult to find a mine of such value anywhere that can be worked at such small cost.

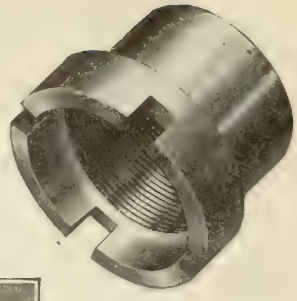
Brown Hematite Ore

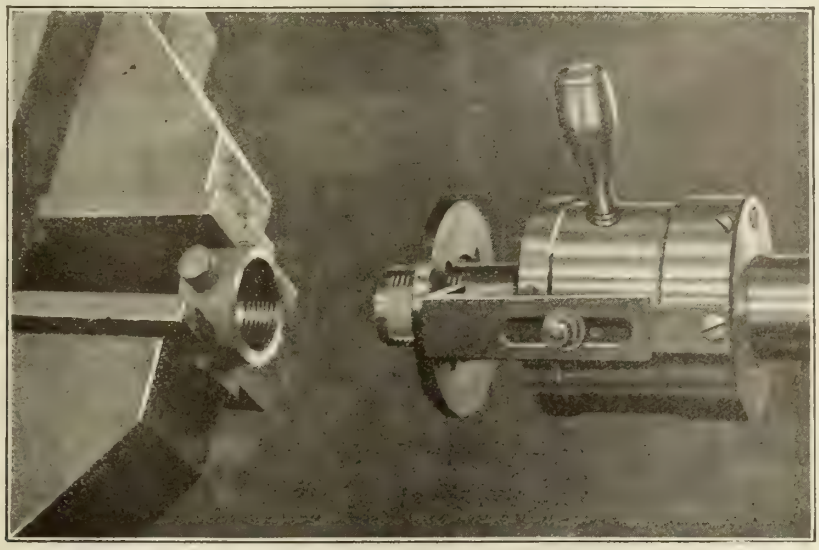
The ore of Bell Island is brown hematite containing fifty-five per cent. of iron. Mixed with other ores, it makes the finest steel. The original company belonged to New Glasgow, Nova Scotia, and were the lessees of the property, which consisted of four grants, each being one mile square. The "Besco" are now the sole operators. Bell Island, as we have stated, is a piece of land six miles long by two miles broad, and the deposits described have been extended by the opening up of others, many of th se running under the bottom of the waters of Conception Bay for considerable distances. In all the years prior to 1895 no person even suspected the mineral treasures it held concealed under the surface of the earth, and it was only the accidental discovery of a fisherman of a piece of ore on his property, which he brought to St. John's as ballast for his boat that led to the opening up and working of this great deposit.

In our next article, which we hope to illustrate with original photographs of the mines, piers, pockets, tramways and buildings, the further story of Bell Island will be continued, with more wealth of detail as to its importance and bearing on the steel trade and manufactures of the world.

50 Per Cent. More Work With a Geometric Collapsing Tap Than With a Solid Tap







Anyone familiar with thread tapping knows what backing out a solid tap each time means. All the expense and annoyance of tapping screw threads with a solid tap have been overcome by the Geometric.

Special Taps for Special Jobs.

Standard Taps for Standard Jobs.

No doubt you and Geometric Screw Cutting Tools are not strangers. You may not realize, however, the number of styles that there are and the different classes of work that they are particularly adapted to.

Whatever the need in Screw Cutting, there is a Geometric to take care of it.

Adjustment to correct diameter each time a thread is tapped. Then chasers collapse automatically, leaving the thread clean cut and perfect.

The Chasers are readily reground, and when finally used up, are renewed at comparatively small cost, leaving the Tap as efficient as when new.

GEOMETRIC AUTOMATIC THREADING TOOLS

For cutting all classes of Screw Threads, internal or external, of any diameter and form.

The Geometric Tool Company

New Haven, Connecticut, U.S.A.

News From the Industrial Field

Loss of $10,000 was caused by fire at the producer house of the Sun Brick Co., Toronto. Fifty hands are out of work temporarily.

New electric power to be brought into production of 2,500 horse power, is proposed for next summer at Windego Falls near Cobalt. The development is owned by Canadian Associated Goldfields.

C. B. Turner, of C. B. Turner & Co., Toronto, recently returned from a convention trip to St. Louis, Mo. Returning via New York he made arrangements to handle several American lines in Canada.

Weston, Ont., has annexed the property occupied by three industrial concerns—Moffats, Limited, Canada Cycle and Motor Co., and the Co-operative Wool Growers. A fixed asessment for 15 years was granted to Moffats, Limited.

Beldam Asbestos Co., formerly at 19 Jarvis St., have removed to larger quarters, 3 Mutual St., Toronto. Mr. Abraham, general sales manager for Canada, states that they have made selling arrangements with a chain of jobbers throughout the Dominion.

Shareholders of Dominion Iron and Steel Co. are asked to authorize an increase of the common stock of the company to $25,000,000. The company is now said to be operating on a profitable basis and furnishing practically full time employment to 23,000 men.

Steel mills and foundries, it was announced some weeks ago in these columns, had been asked to consider preliminary enquiries upon 3,500 box and refrigerating cars for the Canadian National. It is now reported that tenders have been sent out for between eight and fifteen million feet of lumber for car-building purposes.

In giving decision defining conditions under which a railway is entitled to charge demurrage, Justice Audette, at Ottawa, finds that railway is entitled to charge demurrage after a car has been available for unloading by the consignee from a proper and reasonable team track for a period of 48 hours. "It is not necessary thereafter for the railway company to keep the car on a team track to enable it to claim demurrage, and the consignee has no right to ask the railway company to keep his car indefinitely upon a team track, thus paralyzing the business of the railway company," states the judgment.

Imports from Canada to United States increased in value $4,000,000 and exports to Canada declined $1,000,000 in September of this year, states a report from Washington.

W. P. Perrin of W. P. Perrin, Limited Toronto, makers of hydraulic machinery, reports an improved demand for this class of equipment. Not for some time has there been two months' work ahead as at present. The outlook is promising and there are indications that railway requirements are becoming more active.

An Italian-Canadian commercial agreement is now being negotiated between Premier Mussolini of Italy and Hon. W. S. Fielding, Minister of Finance. Under the 1910 agreement Italy gave Canada special rates on woods, furniture, wood pulps, paper, boots and shoes, tools, sewing machines, horses and cattle, fish and cheese.

The following British Columbia companies were recently incorporated: International Electric Co., Ltd., $100,000, Stewart; Burrard Equipment Co., $20,000, Vancouver; Herondale Products Co., Ltd., $50,000, Vancouver; A. J. Johnson Lumber Co., Ltd., $50 000, Vancouver; Brooks-Iowa Lumber Company, $400,000, Vancouver; Vancouver Woodyard Ltd., $20,000, Vancouver; Delaney and Sinclair, Ltd., $20,000, Vancouver.

Although British Columbia produced the bulk of copper mined in Canada, that province has only three small plants manufacturing brass and copper articles, with an annual production of $57,314, as compared with 59 manufacturing plants in Canada, with an annual production value of $13,760 311. The bulk of the manufacturing plants are in Ontario and Quebec. Ontario has 39 plants, producing $6,774,066 worth of goods; Manitoba, 3, producing $955,998; Quebec, 12, $5,525,153; and New Brunswick, 2, producing $477,780.

It is reported that Alberta's total coal output for the first six months of 1922, amounted to 2,404,266 tons, compared with 2,833,075 tons during the same period a year ago. The total output last year was 5,937,000 tons, while 1920 was the banner year for Alberta with 6,908,000 tons mined. The market in Manitoba is steadily developing. Last year it took a half million tons of Alberta coal, practically all domestic. Saskatchewan gets most of its import coal from Alberta, but still imports some anthracite from elsewhere.

Owen Sound Board of Trade is exerting its influence to have some of the Canadian Merchant Marine winter in that harbor this winter. Good harbor and fire protection is available, and there are facilities for repairs.

Lumbering operations are active in all parts of British Columbia at the present time, according to reports received here. The Bucklin Lumber Company is entering on a logging operation, tapping a stand of 80,000,000 feet in the Upper Pitt Valley. The Company hope to have an output of 75,000 feet a day.

Up-to-date there has been somewhat in excess of two millions spent on federal aid highways in New Brunswick, of which amount the federal grants have totalled in the vicinity of $850,000. The gross amount which has been expended this year is approximately $300,000, which is about half of what has been expended in previous years.

A steady reduction in the volume of unemployment is evident through the Maritime Provinces. The chief factors affecting conditions have been the settling down to full time employment at the coal mines, the gathering of the fruit and grain crops, and the general improvement in the manufacturing group of industries, especially steel.

Since 1911 the Quebec Provincial Government has spent over $41,000,000 on roads, according to a statement made by Hon. J. L. Perron. Out of the 40,000 miles of roads, there were 10,000 miles of main roads, divided into leading highways and county roads. The government has so far built 1,500 miles of leading highways, improved 5,000 miles of county roads, and over 8,000 miles of the third class, or local roads.

Seven carloads of glass ware used in the ten hot houses, each 36 ft. x 341 ft., built for Miller & Sons, florists at Concord, a few miles north of Toronto. Twenty more of these houses will be built next year. The glass and steel work was in charge of the King Construction Co., Toronto. Three and three-quarter miles of four-foot rose benches of Ontario cedar were installed by J. S. Knapman, Toronto. The heating plant, by the John Inglis Co., and the power equipment, are said to have cost $200,000. Construction work was begun April 15, and on June 17 the first of 64,000 roses were planted. Cuttings are now being made at the rate of 2,000 daily. It is the intention of Miller & Sons to move their Lauder Ave. plant to Concord eventually.

ATKINS
METAL CUTTING SAWS

Solve your Metal Cutting problems easily, quickly and economically, by adopting the products made by

ATKINS

We make Kwik-Kut Power Hack Saw Machines which use practically the full cutting edge of the Hack Saw Blade at each stroke; Metal Cutting Band Saw Machines for general shop work, cutting all classes of metal up to 12 x 14 inches.

Your requirements for Metal Cutting Circular Saws can be supplied promptly and we solicit a trial of our "AAA" Non-Breakable and Power Hack Saw Blades and Frames.

ONTARIO CONCERN EXTENDS TO QUEBEC

QUEBEC, Que.—Standard Steel Co., Welland, will establish a branch plant in Quebec. It is recognized by building contractors that the company have shown some foresight in entering the Quebec field to manufacture steel for bridge and general construction purposes. Apart from the Dominion Bridge Company at Lachine, there is only one such plant in Quebec, the Eastern Steel Company, which was established about twelve years ago. A small plant was then equal to the demand. Within the past ten years there has been quite a large demand for steel for bridges and public buildings in this district. In addition there is a growing demand for steel in connection with the construction of hotels and schools as well as for the more important private dwellings. The danger from fire and the increased cost from insurance have improved the demand for steel.

The addition to the Chateau Frontenac including the twenty-storey tower, in course of erection, calls for 28,000 tons of steel, which is being furnished by the Dominion Bridge Co.

There are abundant ore deposits along the ranges of the north shore, extending from Les Embankment. The iron is impregnated with titanic acid, which has prevented development. This ore is now going to Niagara in large quantities, and with the electric process, the titanic acid can be extracted and used as a by-product.

The Standard Steel Co., which will operate here under the French name of Le Construction Cie., Limitee, expect to erect their plant next spring on a location two miles from the city but with good railway connections. They will employ forty to fifty men and will handle structural steel and ornamental iron castings.

Imported pig iron, laid down in Quebec, costs $32.75 per ton, while Hamilton pig costs $36 per ton. There are only two large foundries in Quebec manufacturing machinery and castings—Terreau and Racine and the Drolet Foundry and Machine Co. These two shops use on an average of 1,200 tons of pig iron annually, one half of which is imported from abroad and the other half from Hamilton. There are no brass foundries in Quebec. Castings are brought from Ontario to quite an extent and also from the United States. Terreau and Racine do the largest business in Quebec. They store plates and machinery and also deal largely in all classes of stoves and furnaces. Their turnover in 1921, which the partner says was a fair year, amounted to $1.600,000. Their constant stock is valued at $600,000 in all classes of goods used in construction.

Consumers' Gas Co., Toronto, are considering the erection of an additional unit to provide for increased consumption. Considerable steel construction is called for.

Electroplax Co.'s factory at Mount Dennis, Ont., was destroyed by fire Nov. 13, the loss being placed at $100,000; insurance, $60,000. The plant was used for the manufacture of electrical insulation equipment.

Permits for new buildings to cost $662,000 were recently issued in Toronto. These include the new Jarvis collegiate to cost $500,000, and an addition to Malvern Ave. school to cost $25,000. The list include 39 dwellings, 34 garages, and 3 stores.

It now rests with the Imperial and Federal governments whether guarantees are to be provided looking to the establishment of an iron and steel industry in British Columbia. An investigation of the ore resources of the province may be instituted.

Massey-Harris plant, Brantford, reflects improved industrial conditions by the addition of from 250 to 300 men to the present staff of 500. The statement is made that this industry expects to have a busy winter. Other firms there report encouraging prospects.

That Canada possessed great trade advantages in Colombia and Venezuela, as well as other Latin-American countries, is the opinion of Edward C. Austin, pioneer trade agent. These countries had shown strong development since the opening of the Panama canal. This market is closer to Toronto than is Calgary.

As indicating the activity in woodworking machinery the Garlock Machinery Co., Toronto report that sales during the past two months have exceeded those of the preceding months of the year. Metal working equipment, however, remains quiet, although enquiries give reason for optimism.

ELEVATOR LUBRICATION

The problem of lubrication of elevator machinery is becoming of considerable importance to the engineering profession to-day. The ever-increasing demand for elevator service, as higher buildings are becoming more and more necessary to house the executive offices of our industries and store their products, has eliminated the heretofore popular idea that elevator machinery, especially of the electric type, could be lubricated in much the same manner as other types of gearing and general motor driving mechanisms. There are certain pertinent operating features which prevail that demand considerable cooperation between the elevator engineer and lubricating oil manufacturers, and careful attention must be paid to these details.

WILLIAM JESSOP & SONS TO BUILD IN CANADA

REPORTS are current in the Toronto steel market that William Jessop & Sons, steel manufacturers, Sheffield, Eng., are preparing to locate a branch factory in Canada. Enquiry at their Toronto office regarding the matter, brought an emphatic statement that there was absolutely nothing to give out at the present time and that rumors indicated a somewhat more extensive outside, and hence unreliable, knowledge of the Company's affairs than could be claimed by their own officials.

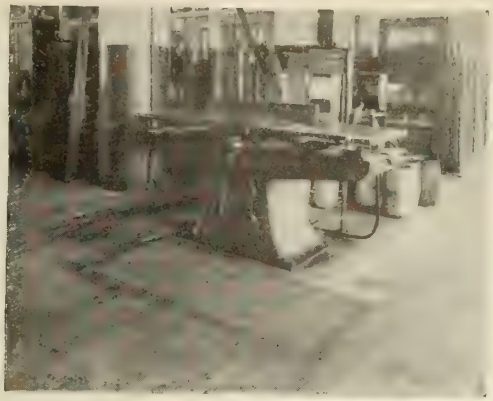
It has been common knowledge that, for some time, this firm has considered the advisability of a Canadian plant but nothing definite has emerged. Present reports have it that methods of financing the Canadian proposition were actually being considered and that the plan would involve the taking over of a going Canadian plant with which would be incorporated the Jessop lines of steel. This was done successfully in connection with the introduction to Canada of the English Electric Co. It is a plan that has merit since it makes available an equipment and organization familiar with Canadian methods and conditions.

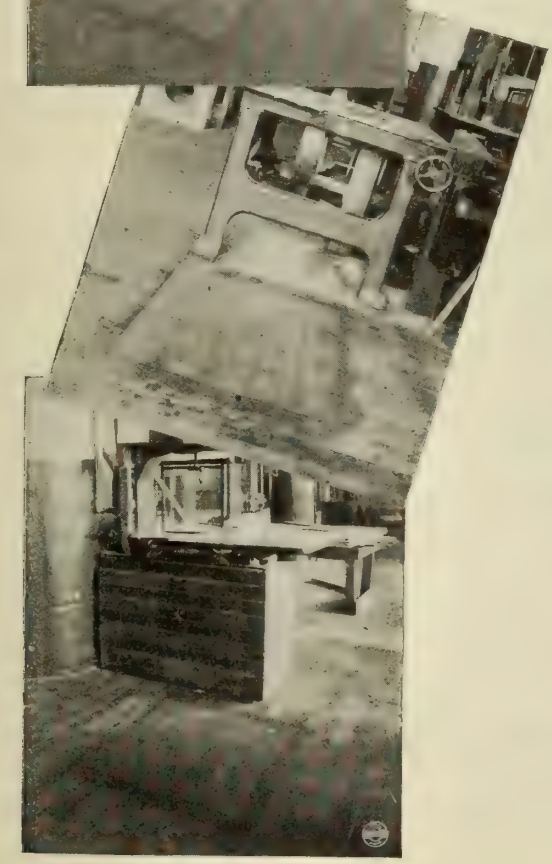
William Jessop & Sons opened their Toronto office some thirty years ago. At their "Brightside Works," Sheffield, their steels have been made since 1775. They are said to have a line that is most adaptable for engineering purposes, whether the product be a twist drill or a 60-ton casting or massive forging. Four typical industries in which their products have figured largely are fine toolmaking, shipbuilding, machine tool work and automobile engineering. It may be that the possibilities of the motor car industry, from a domestic as well as an export point of view, have some appeal to the Company. Among their specialties are crankshafts of nickel-chome steel for any type of engine.

NEGOTIATING FOR BALDWIN

Bethlehem Steel Corporation, as hinted in these columns some weeks ago, are negotiating for the purchase of the plant in Toronto of the Canadian Baldwin Steel Corporation. It is learned at the office of the latter that while the deal is going forward, there is nothing to be made public in that connection and that reports in a morning newspaper, commenting upon details as to price, were absolutely erroneous.

The Baldwin plant is idle at present although there are large stocks of black and galvanized sheets on hand which are reported to be moving freely. While some of the equipment of the plant, particularly that of the rolling mill, is of American make, the galvanizing equipment is British. The outstanding cause of the plant's idleness at the present time is the inability to secure adequate supplies of quantity and quality to keep the plant running steadily on requirements of the Canadian trade.





NO MORE SLIPPING

Wood Floors in wood-working shops become smooth and dangerous when partly covered by sawdust and shavings.

Machine shop floors become slippery from oil, grease and other lubricants. A permanent non-slip surface may be made with

ALUNDUM Safety Tile

Always slip-proof, never wears smooth. Flush with the floor, nothing to trip on. Neither grease, oil, shavings nor sawdust affect its slip-proof surface. Easy to install.

Alundum tile contains the same material as used in the manufacture of Norton Alundum grinding wheels.

In place of a Height Gage

Where there is only an occasional use for a Height Gage, this Starrett Height Gage Attachment serves every purpose of the more expensive tool. By inserting a Starrett Inside Micrometer into the steel base, this tool becomes an accurate, reliable gage—all at only a part of the cost of the ordinary Height Gage. A slight turn of the knurled screw instantly clamps or releases the micrometer from the base.

Write for Catalog No. 22"3" and the Supplement describing the new Starrett Tools.

Why Don't You Write?

HARDLY a week passes that Canadian Machinery does not receive copies of this paper returned by the postal authorities because of the change in firm names or the address of some whose names are on the mailing list. Sometimes complaints reach us of the non-delivery of mail matter. It is not till the receipt of such complaints or the return of the paper, as the case may be, that we obtain any knowledge of the changes or removals of persons or firms. The adoption of the co-operative spirit on your part by notifying changes would make things a good deal more pleasant for both parties. The MacLean Publishing Co. want their mailing list to be in such shape that they will be able to render the perfect service to their subscribers. There is a lot of valuable trade matter mailed by this company and if you don't receive it—well, the fault is entirely yours.

NEW AIR-TIGHT BLAST GATE

Light, Strong, Compact. Inexpensive. Quick-Acting. Threaded or Flanged Connections.

Eliminates excessive valve costs and secures worthwhile savings in many difficult valve control operations, among which are the following:

Air and gases of various kinds
Blast furnace coal and lime dust.
Combating back pressures
Distillation processes.
Pulverized coal
Chemicals handled thru pipes
Gas engine exhaust lines.
Soot chutes
Starch.

"P M S"

THE "RED RIBBON" BELT

Greater Adhesion to Pulley
Even Pliability
Great Strength and
Remarkable Resistance to Heat, Cold and Moisture

"Greater adhesion" means for you a greater percentage of your costly power delivered to the machines; "even pliability" means smooth, uniform running; "great strength" means freedom from interrupted production for belt adjustments, repairs or replacements; "the remarkable resistance to heat, cold and moisture" means efficiency, even under conditions once considered too harsh for this type of belt.
